HAZELL, WATSON & VINEY, LTD.
52, LONG ACRE, LONDON, W.C.2

INDEX TO VOLUME II, 1939

REFERENCES AND ABBREVIATIONS

In search of a given subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings. Institutions and Corporations with the right to the prefix Royal will be found under that prefix, with the exception of Hospitals, which will be found under that heading, and Medical Societies, which are separately indexed under Societies. All Universities are indexed under the word University. (*L*) = *Annotation*, (*C*) = *Correspondence*, (*LA*) = *Leading Article*, (*ML*) = *Medico-legal*, (*NT*) = *New Inventions*, (*O*) = *Obituary*, (*PCP*) = *Panel and Contract Practice*, (*PI*) = *Parliamentary Intelligence* and (*R*) = *Review*.

A Concordance of page numbers and dates of issue will be found on page xxiii

THE MECHANISM OF DIABETES MELLITUS*

BY H P HINSWORTH, MD Lond., FRCP
DEPUTY DIRECTOR MEDICAL UNIT UNIVERSITY COLLEGE HOSPITAL, LONDON

I

IN delivering these Goulstonian lectures I shall attempt to fulfil the spirit, if not the letter, of the conditions laid down by Dr Goulston when in 1632 he made his gift to this college He directed that his gift should be used to enable one of the younger fellows to demonstrate the results of a disease by dissection of a dead body My purpose in this and the subsequent two lectures will be to demonstrate the mechanisms of a disease by describing a sequence of experimental observations on the living subject I can approach this task in no better way than by first describing the clinical observations which originally directed my attention to the significance of one of the most important of these mechanisms

In the autumn of 1930 I had under my care a woman, aged 30, suffering from severe diabetes mellitus, and I was struck by the fact that, although she would in a short time lose large quantities of sugar in the urine, this loss of sugar from the body did not reduce the blood sugar level To test this observation I produced a profuse and periodic diuresis in the patient by giving her quantities of water to drink, and I found that the blood sugar remained stationary, even though the urinary excretion of sugar varied widely This observation was the more striking because in the periods of profuse diuresis more sugar would be washed out of the body in half an hour than was contained in the whole volume of the patient's blood, and yet the blood sugar remained steady at its original level Pursuing these observations further, I investigated the effect of loss of sugar in the urine on the rise of blood-sugar after the oral administration of glucose First, the degree of glycosuria and the blood sugar level in the fasting state were determined, 50 g of glucose was then given by mouth, and afterwards sufficient water was given to produce a continued diuresis The sugar content of the blood and that of the urine were estimated at regular intervals It was found that, although at the end of five hours an excess of 56 g of sugar had appeared in the urine, the blood sugar level was still 60 mg per 100 c cm higher than before the glucose had been given Similar observations were made on other patients and it was further found that the course of the blood sugar tolerance curve was uninfluenced by the degree of glycosuria (fig 1) By varying the diuresis the amount of sugar excreted in the urine was varied at different times during the course of the curve, but nevertheless the smooth rise and fall of the curve continued without wavering [37] To determine if the same significance could be attached to the blood sugar value in the normal person the same experiments were repeated on persons with renal glycosuria It is generally conceded that the metabolism in such cases is normal, and that the glycosuria is merely the result of a harmless functional peculiarity of the kidney Owing to the relatively small loss of sugar in the urine in renal glycosuria the results were not so dramatic as those obtained on diabetics, they were, however, sufficient to show clearly that the course of the blood-sugar in these cases also was not affected by variations in the amount of glycosuria [37]

These observations appear to me to be very significant They show that, within the limits of the experiments, the blood sugar level is unaffected by loss of sugar in the urine, even though glycosuria be so profuse that more sugar is removed from the body in the period of observation than is contained in the blood at any particular moment This can only mean that outflow of sugar into the urine is being actively compensated by an equivalent inflow of sugar into the blood This observation is incompatible with the old idea that the increased amount of sugar in the diabetic's blood represents a passive accumulation of unutilisable carbohydrate It suggests that at any particular time the blood sugar value is fixed by the body at a particular level, and that the maintenance of the blood-sugar at this particular level, whether in the fasting state or in the course of hyperglycæmia, is so important in the metabolism of the body that attempts to change it by physical means are swiftly and accurately countered The constancy of the fasting blood-sugar level in normal men and animals has been commented on by numerous observers The failure to realise that under constant dietary conditions the blood sugar tolerance curve after a dose of glucose also remains remarkably constant [42] can only be attributed to the casual way in which this test is usually performed. For purposes of studying the blood sugar tolerance accurate curves are necessary, and these require not only that frequent samples of blood be taken but also that the test must be carried out under conditions as strictly controlled as those required for estimation of the basal metabolic rate All the blood sugar curves reported in this paper have been carried out under such conditions The accurate measurement of the blood sugar tolerance curves thus obtained presented some difficulty until it was found that, although the contour of the curves obtained under constant conditions varied, the area bounded by these curves above the fasting blood-sugar level remained approximately constant [42] Table I shows that under constant conditions the area of the glucose tolerance curve remains remarkably constant It is difficult to believe that such constancy is without significance

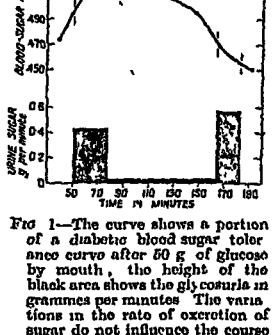

FIG 1—The curve shows a portion of a diabetic blood sugar tolerance curve after 50 g of glucose by mouth, the height of the black area shows the glycosuria in grammes per minute The variations in the rate of excretion of sugar do not influence the course of the blood sugar curve

* The Goulstonian lectures for 1939 delivered before the Royal College of Physicians of London on March 2, 7, and 9 Lects II and III, together with the references will appear in later issues

as due to the plethora of glucose in the blood increasing utilisation of sugar More recently Wierzuchowski [137 138] has shown that in normal animals the assimilation and oxidation of ingested glucose increase with the rate of its infusion and the rise of blood sugar up to a high limiting value Increase in the height of the blood sugar level similarly favours the action of insulin in normal subjects [55 61 66 119] Under constant conditions of diet the higher the level of the fasting blood sugar the greater the effect of a standard dose of insulin in depressing the blood sugar This relation between fasting blood sugar level and insulin effect has been closely investigated by Scott and Dotti,[119] who have shown that the effect of a standard dose of insulin in depressing the blood sugar is proportional to the height of the fasting blood sugar level on which it acts Recently Dr R B Kerr and I [66] have shown that a similar relationship governs the action of insulin in suppressing alimentary hyperglycæmia Under constant dietary conditions the greater the glucose tolerance curve the greater the effect of a standard dose of insulin in suppressing the glucose tolerance curve - It thus appears that, when the head of pressure of sugar in the blood is high, sugar utilisation and insulin action are facilitated, whereas, when the head of pressure of sugar is low, sugar utilisation and insulin action are retarded In healthy subjects the fasting blood sugar level varies relatively little The blood sugar tolerance curve of healthy subjects however, varies widely according to the different conditions under which it is obtained, and consideration of these variations and of the phenomena associated with them throws considerable light on the purpose behind their changes

ASSOCIATION BETWEEN INSULIN SENSITIVITY AND GLUCOSE TOLERANCE

It was noted by Claude Bernard [11] that when a carbohydrate rich meal was given to a starving dog glycosuria often followed In 1913 Bang [9] showed that starvation caused a high blood sugar tolerance curve—i e , lowered the tolerance of the animal for glucose Later Adlersberg and Porges [2 3] and Sweeney [129] showed that high fat diets caused a high tolerance curve, whereas high carbohydrate diets caused a low tolerance curve I have shown

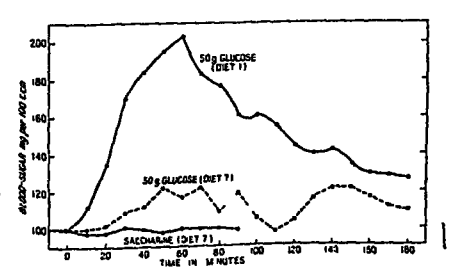

FIG 2—Three blood-sugar curves from the same healthy subject The curve on diet 1 shows the effect of a low carbohydrate diet on the glucose tolerance curve produced by oral administration of 50 g glucose; the curve on diet 7 shows the effect of an equicalorie high carbohydrate diet The saccharine curve is a control experiment showing that no rise of blood sugar follows the drinking of a solution of saccharine or is caused by the experimental technique [62]

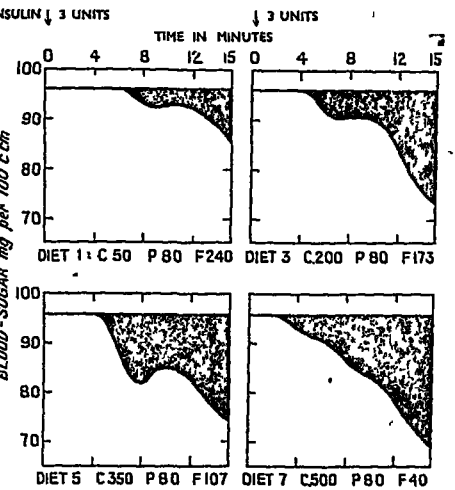

INSULIN ↓ 3 UNITS
↓ 3 UNITS
TIME IN MINUTES

DIET 7 C 500 P 80 F40

FIG 3—Four insulin-depression curves, after injection of 3 units of crystalline insulin solution intravenously, obtained from the same healthy subject when taking diets containing different amounts of dietary carbohydrate [62]

that the sole dietary factor governing sugar tolerance is the absolute amount of carbohydrate in the preceding diet, with progressive restriction of dietary carbohydrate there is progressive impairment of sugar tolerance, which is shown by a corresponding heightening of the blood sugar tolerance curve [62] The results in a typical experiment are shown in fig 2, and a series of such curves measured by the method of areas is shown in table I It will be seen that, while the size of the areas depends on the composition of the preceding diet, repeated tests under constant dietary conditions show a remarkable degree of constancy It is therefore possible to vary the height to which the blood sugar rises after ingestion of a constant dose of glucose by varying the carbohydrate content of the preceding diet, but, if the dietary carbohydrate is maintained constant, the blood sugar tolerance curve remains constant also

The action of insulin in depressing the blood sugar level in normal and diabetic subjects is perhaps its most characteristic effect, and it is now realised that this action is not fixed but can be varied. When in the second of two tests the same dose of insulin depresses the blood sugar more rapidly than in the first, the insulin sensitivity of that subject is said to have increased It should be emphasised that the term "insulin sensitivity" applies only to the rate at which the blood sugar is depressed. The speed of return to normal levels is irrelevant, depending on factors other than insulin action The rate at which a standard dose of insulin depresses the fasting blood sugar level depends on the composition of the preceding diet [2 62 121] and as in the case of the glucose tolerance curve, it is the carbohydrate content of this diet which is the determining factor With progressive restriction of dietary carbohydrate there is progressive diminution in the effect of a standard

as due to the plethora of glucose in the blood increasing utilisation of sugar More recently Wierzuchowski[127 128] has shown that in normal animals the assimilation and oxidation of ingested glucose increase with the rate of its infusion and the rise of blood sugar up to a high limiting value Increase in the height of the blood sugar level similarly favours the action of insulin in normal subjects[83 61 66 119] Under constant conditions of diet the higher the level of the fasting blood sugar the greater the effect of a standard dose of insulin in depressing the blood sugar This relation between fasting blood sugar level and insulin effect has been closely investigated by Scott and Dotti,[118] who have shown that the effect of a standard dose of insulin in depressing the blood sugar is proportional to the height of the fasting blood sugar level on which it acts Recently Dr R B Kerr and I[60] have shown that a similar relationship governs the action of insulin in suppressing alimentary hyperglycæmia Under constant dietary conditions the greater the glucose tolerance curve the greater the effect of a standard dose of insulin in suppressing the glucose tolerance curve - It thus appears that, when the head of pressure of sugar in the blood is high, sugar utilisation and insulin action are facilitated, whereas, when the head of pressure of sugar is low, sugar utilisation and insulin action are retarded In healthy subjects the fasting blood sugar level varies relatively little The blood sugar tolerance curve of healthy subjects, however, varies widely according to the different conditions under which it is obtained, and consideration of these variations and of the phenomena associated with them throws considerable light on the purpose behind their changes

ASSOCIATION BETWEEN INSULIN SENSITIVITY AND GLUCOSE TOLERANCE

FIG 3—Four insulin-depression curves, after injection of 3 units of crystalline insulin solution intravenously, obtained from the same healthy subject when taking diets containing different amounts of dietary carbohydrate[62]

that the sole dietary factor governing sugar tolerance is the absolute amount of carbohydrate in the preceding diet, with progressive restriction of dietary carbohydrate there is progressive impairment of sugar tolerance, which is shown by a corresponding heightening of the blood sugar tolerance curve[62] The results in a typical experiment are shown in fig 2, and a series of such curves measured by the method of areas is shown in table I It will be seen that, while the size of the areas depends on the composition of the preceding diet, repeated tests under constant dietary conditions show a remarkable degree of constancy It is therefore possible to vary the height to which the blood sugar rises after ingestion of a constant dose of glucose by varying the carbohydrate content of the preceding diet, but, if the dietary carbohydrate is maintained constant, the blood sugar tolerance curve remains constant also

The action of insulin in depressing the blood sugar level in normal and diabetic subjects is perhaps its most characteristic effect, and it is now realised that this action is not fixed but can be varied When in the second of two tests the same dose of insulin depresses the blood sugar more rapidly than in the first, the insulin sensitivity of that subject is said to have increased. It should be emphasised that the term "insulin sensitivity" applies only to the rate at which the blood sugar is depressed The speed of return to normal levels is irrelevant, depending on factors other than insulin action The rate at which a standard dose of insulin depresses the fasting blood-sugar level depends on the composition of the preceding diet[1 6 43 121] and as in the case of the glucose tolerance curve it is the carbohydrate content of this diet which is the determining factor With progressive restriction of dietary carbohydrate there is progressive diminution in the effect of a standard

Experiments on carbohydrate metabolism in animals provide numerous examples of this maintenance of the sugar in the blood at a particular level; they also provide examples of the disastrous results to the organism when the bodily mechanisms do not maintain this level. From the numerous animal experiments available two illustrative examples may be chosen: (1) the hypophysectomised animal fails to maintain the blood-sugar level partly, if not entirely, because of the diminished inflow of sugar from the liver to the blood; and (2) in phloridzin poisoning the animal fails to maintain the necessary blood-sugar level because of the excessive outflow of sugar into the urine

(1) When food is withheld from hypophysectomised animals the blood-sugar falls [26 33] and ultimately

TABLE I—CONSTANCY OF THE AREA DEMARCATED BY THE SUGAR-TOLERANCE CURVE WHEN A DIET WITH CONSTANT AMOUNT OF CARBOHYDRATE IS BEING TAKEN

Subject	Diet			Area of glucose tolerance in mg /min
	Carbohydrate	Protein	Fat	
I	100	80	218	6600 6500

The glucose-tolerance areas were terminated at the shortest time taken by any glucose-tolerance curve on the particular subject to return to normal. The interval between different glucose-tolerance tests on the same diet varied from three days to nine weeks. The figures demonstrate that the greatest discrepancies between duplicate experiments are found when a low-carbohydrate diet is being taken [66]

death results. It has been shown by Cope [22] that this spontaneous fall of blood-sugar does not take place before the liver-glycogen is practically exhausted. Up to this time the blood-sugar is maintained at normal levels, then, the source of sugar being exhausted, the blood-sugar falls to hypoglycæmic levels. There is strong evidence that in the absence of the hypophysis the ability to manufacture glucose from non-carbohydrate sources and consequently the ability of the starving animal to replenish its liver-glycogen are limited. It is therefore of particular interest that no attempt is made to eke out the supply of liver-glycogen by adjusting the blood-sugar level to markedly subnormal values. Until the liver-glycogen is used up, the blood-sugar is sustained at normal values; then it plunges down to low levels and death results.

(2) After administration of phloridzin to a normal animal, although there are effects on tissues other than the kidney,[103 134] the effects of the excessive glycosuria dominate the picture.[101 143] When phloridzin is given to a fasting normal animal, profuse glycosuria appears and continues for several hours before there is any change in the blood-sugar level. Then the blood-sugar level begins to fall, and, when this happens, it is found that the glycogen in the liver has diminished to minimal amounts. At the same time the increasing excretion of urinary nitrogen indicates an accelerating breakdown of body proteins while an increasing ketonuria and a fall of the respiratory quotient denote that the body is now driven to obtain its energy mainly if not exclusively from the combustion of fat.[104] The dependance of the sequence of events on the fall of blood-sugar is shown by the effect of the administration of glucose in rapidly restoring the animal to normal.[32] It appears that the fall of blood-sugar which takes place as a result of the excessive glycosuria is of such serious import to the economy of the body that in the attempt to sustain the blood-sugar at normal levels the proteins of the body itself are sacrificed to increase the production of endogenous sugar.

The foregoing results indicate that the fasting blood-sugar levels of the normal and of the diabetic are under given conditions actively maintained within certain levels, and that the degree of alimentary hyperglycæmia, as measured by the blood sugar tolerance curve, is under given conditions also actively maintained within definite limits. It is extremely unlikely that a constancy of this nature can be fortuitous, and it seems allowable to suggest that the blood-sugar level, in the circumstances existing at any particular time, is that which approaches nearest to the optimum for the needs of the body. This raises two questions. why in different circumstances should the optimal blood-sugar value be fixed at different levels, and how are the changes in optimal blood-sugar level brought about? The consideration of these questions will be facilitated if we anticipate the discussion of some of the evidence that follows and formulate now a working hypothesis. This can then be applied to the experiments as they are presented and its development into a theory followed. Utilisation of sugar by the tissues increases in proportion with the height of the blood sugar level.[87 126 137 138] It is suggested that the height of the blood-sugar level can be regarded, metaphorically, as a head of pressure of sugar in the blood. In health this head of pressure is within what we recognise as normal limits and ensures that in normal circumstances utilisation of carbohydrate by the tissues proceeds at an adequate rate. If however, the ability of the tissues to use sugar is diminished—e.g., by either lack of insulin or impairment of insulin action—compensation is made through an appropriate increase in the head of pressure of sugar in the blood. The rate of utilisation of sugar by the tissues is thus maintained relatively constant.[57] Using this hypothesis as a guide, we can now examine the changes in blood-sugar level and the associated alteration in bodily function which take place in normal and abnormal carbohydrate metabolism, and, if this guide prove to be true, we can hope eventually to construct a theory which renders these changes and their associated alterations intelligible.

SIGNIFICANCE OF VARIATIONS IN THE BLOOD-SUGAR LEVEL

We can best approach the question of why the blood-sugar level varies by considering the effects of manipulating the height of the blood-sugar level on sugar utilisation and on insulin action. The effect of the blood-sugar level on sugar utilisation in normal animals is well established. After ingestion of glucose the respiratory quotient and the consumption of oxygen rise, and Lusk [87] has explained this effect

as due to the plethora of glucose in the blood increasing utilisation of sugar More recently Wierzuchowski[137 138] has shown that in normal animals the assimilation and oxidation of ingested glucose increase with the rate of its infusion and the rise of blood sugar up to a high limiting value Increase in the height of the blood sugar level similarly favours the action of insulin in normal subjects[55 61 66 119] Under constant conditions of diet the higher the level of the fasting blood sugar the greater the effect of a standard dose of insulin in depressing the blood sugar This relation between fasting blood sugar level and insulin effect has been closely investigated by Scott and Dotti,[119] who have shown that the effect of a standard dose of insulin in depressing the blood sugar is proportional to the height of the fasting blood sugar level on which it acts Recently Dr R B Kerr and I[66] have shown that a similar relationship governs the action of insulin in suppressing alimentary hyperglycæmia Under constant dietary conditions the greater the glucose tolerance curve the greater the effect of a standard dose of insulin in suppressing the glucose tolerance curve - It thus appears that, when the head of pressure of sugar in the blood is high, sugar utilisation and insulin action are facilitated, whereas, when the head of pressure of sugar is low, sugar utilisation and insulin action are retarded In healthy subjects the fasting blood sugar level varies relatively little The blood sugar tolerance curve of healthy subjects, however, varies widely according to the different conditions under which it is obtained, and consideration of these variations and of the phenomena associated with them throws considerable light on the purpose behind their changes

ASSOCIATION BETWEEN INSULIN SENSITIVITY AND GLUCOSE TOLERANCE

It was noted by Claude Bernard[11] that when a carbohydrate rich meal was given to a starving dog glycosuria often followed In 1913 Bang[9] showed that starvation caused a high blood sugar tolerance curve—i e , lowered the tolerance of the animal for glucose Later Adlersberg and Porges[2 3] and Sweeney[120] showed that high fat diets caused a high tolerance curve, whereas high carbohydrate diets caused a low tolerance curve I have shown

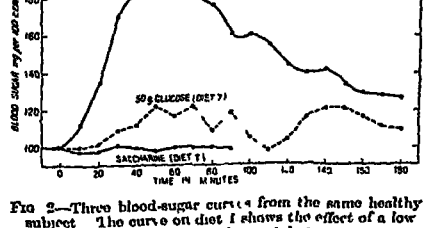

FIG 2—Three blood-sugar curves from the same healthy subject The curve on diet 1 shows the effect of a low carbohydrate diet on the glucose tolerance curve produced by oral administration of 50 g glucose , the curve on diet 7 shows the effect of an equicaloric high carbohydrate diet The saccharine curve is a control experiment showing that no rise of blood sugar follows the drinking of a solution of saccharine or is caused by the experimental technique[62]

FIG 3—Four insulin-depression curves, after injection of 3 units of crystalline insulin solution intravenously, obtained from the same healthy subject when taking diets containing different amounts of dietary carbohydrate[62]

that the sole dietary factor governing sugar tolerance is the absolute amount of carbohydrate in the preceding diet , -with progressive restriction of dietary carbohydrate there is progressive impairment of sugar tolerance, which is shown by a corresponding heightening of the blood sugar tolerance curve[62] The results in a typical experiment are shown in fig 2 and a series of such curves measured by the method of areas is shown in table I It will be seen that, while the size of the areas depends on the composition of the preceding diet, repeated tests under constant dietary conditions show a remarkable degree of constancy It is therefore possible to vary the height to which the blood sugar rises after ingestion of a constant dose of glucose by varying the carbohydrate content of the preceding diet , but, if the dietary carbohydrate is maintained constant, the blood sugar tolerance curve remains constant also

The action of insulin in depressing the blood sugar level in normal and diabetic subjects is perhaps its most characteristic effect, and it is now realised that this action is not fixed but can be varied When in the second of two tests the same dose of insulin depresses the blood sugar more rapidly than in the first, the insulin sensitivity of that subject is said to have increased It should be emphasised that the term "insulin sensitivity" applies only to the rate at which the blood sugar is depressed The speed of return to normal levels is irrelevant depending on factors other than insulin action The rate at which a standard dose of insulin depresses the fasting blood sugar level depends on the composition of the preceding diet[2 3 62 121] and as in the case of the glucose tolerance curve, it is the carbohydrate content of this diet which is the determining factor With progressive restriction of dietary carbohydrate there is progressive diminution in the effect of a standard

dose of insulin on the fasting blood-sugar level, with the result that the blood-sugar is depressed more slowly and to a less extent, and the area traced out by the insulin-depression curve below the fasting blood-sugar level diminishes.[62] A typical experiment is given in fig. 3, which shows that, as the carbohydrate content of the diet is increased, the sensitivity of the subject to insulin increases, with the result that each unit of insulin disposes of more sugar in a given time. Thus increasing the dietary carbohydrate has a twofold effect: it improves the blood-sugar tolerance curve, and it improves the sensitivity to insulin. This association appears to be invariable. Before, however, considering why these changes in the sugar-tolerance curve are correlated with similar changes in insulin sensitivity it is necessary first to consider if the variations in sugar tolerance resulting from dietary changes can be explained by variations in the secretion of pancreatic insulin.

Closely related to the effect of dietary carbohydrate on the sugar-tolerance curve is the phenomenon first described by Hamman and Hirschmann,[53] who showed that periodic ingestion of constant amounts of glucose led to progressively smaller rises of the blood-sugar. This work has been confirmed and extended by Staub[128] and by Traugott,[132] by whose names the phenomenon is now usually known. The accepted explanation of the Staub-Traugott phenomenon is that each successive dose of glucose provokes an increased secretion of insulin. At first sight the explanation appears very probable, for there is considerable evidence that a rise of blood-sugar is an adequate stimulus to the secretion of pancreatic insulin. Soskin et al.,[121] however, have shown that in a depancreatised dog, receiving a constant injection of insulin sufficient to maintain its blood-sugar at normal levels, the periodic injection of constant doses of glucose still leads to progressively smaller rises of blood-sugar. The progressive improvement in sugar tolerance can thus be explained without postulating a progressive increase in the secretion of pancreatic insulin. Studying the same phenomenon I showed that repeated injections of glucose caused a corresponding increase in the insulin sensitivity of the animal.[61] It therefore appears that the Staub-Traugott phenomenon must be explained not as the result of a progressively increasing secretion of endogenous insulin but as the effect of a constant amount of insulin in the presence of a progressively increasing sensitivity to insulin.

The correlation between the changes in glucose tolerance and in sensitivity to insulin induced by change in the carbohydrate content of the diet has been indicated above. On closer examination this correlation is found to be surprisingly exact. If the effects of several diets differing in carbohydrate content are tested on the glucose-tolerance curve and on the insulin-depression curve, it is found that changes in glucose tolerance are accurately correlated with proportionately equal changes in sensitivity to insulin. In other words, dietary changes in glucose tolerance can be adequately accounted for by changes in the sensitivity of the subject to his own pancreatic insulin.[62] This conclusion carries an implication which accords with the experiments of Soskin quoted above: that the amount of insulin secreted by the normal pancreas in response to ingestion of a standard dose of glucose is constant; and it suggests further that the secretory response of the islets of Langerhans to a plethora of glucose is of the "all or none" type.

It is now possible to see a purpose underlying the variations in the glucose-tolerance curve which result from changes in dietary carbohydrate. It has been shown that under constant conditions the effect of insulin in depressing the fasting blood-sugar level, or in suppressing the rise of blood-sugar after ingestion of glucose, increases with the height of the blood-sugar. After restriction of dietary carbohydrate the sugar-tolerance curve rises to levels higher than normal. Under the same conditions sensitivity to insulin is depressed. It will be seen that this change in the sugar-tolerance curve is such that it tends to counteract the effect of diminished sensitivity to insulin. When insulin sensitivity becomes impaired, there is a compensatory increase in the head of pressure of sugar in the blood during the course of the sugar-tolerance curve. This facilitates the action of insulin on the blood-sugar, with the result that the effect of the insulin secreted by the pancreas remains unimpaired. Direct evidence in favour of this view has recently been obtained.[66] It was found that, when insulin sensitivity was constant, the effect of a standard dose of insulin in suppressing the glucose-tolerance curve was proportional to the height of the curve on which the insulin acted. Now, the size of the blood-sugar tolerance curve can be varied by varying the carbohydrate content of the preceding diet, but this procedure also changes the sensitivity to insulin. In each of the different conditions of insulin sensitivity produced it was found that the effect of a standard dose of insulin in suppressing the blood-sugar curve remained constant and was no longer proportional to the height of the curve. Thus the same amount of blood-sugar was removed by the standard dose of insulin when the curve was high and the sensitivity to insulin low as when the curve was low and the sensitivity to insulin high. The increased head of pressure of sugar in the blood had compensated the diminished sensitivity to insulin. If the conditioned variations in the blood-sugar which we have been considering have as their object the neutralising of the effect of changes in insulin sensitivity, it is important to know what would be the effect of such variations in sensitivity to insulin if no such neutralising mechanism existed.

INSULIN SENSITIVITY AND THE UTILISATION OF BLOOD SUGAR BY THE PERIPHERAL TISSUES

The peripheral action of insulin was clearly demonstrated by Mann and Magath[94] and by Burn and Dale.[18] Mann and Magath showed that after hepatectomy in dogs insulin produced a fall of blood-sugar comparable with that observed in normal animals; and Burn and Dale demonstrated that insulin caused the disappearance of large quantities of infused sugar in decapitated eviscerated preparations. This work was extended by the experiments of Frank, Nothmann, and Wagner,[46] who showed that injection of insulin, both in the intact and in the depancreatised dog, caused an increase in the abstraction of sugar from the blood, as shown by an increase in the arteriovenous (A-V) sugar difference, and moreover that after intra-arterial injection of insulin the A-V sugar difference was most obvious in the limb supplied by that artery. There is now no doubt that the action of insulin in the peripheral tissues is not constant but depends on other factors. It has been shown, for example, that after treatment with extracts of the anterior-pituitary gland the action of insulin is greatly reduced both in promoting deposition of muscle-glycogen in eviscerated preparations[98] and in accelerating the fall of blood-sugar in rabbits in which the liver is excluded.[69] Direct evidence that the carbohydrate content of the preceding diet influences the uptake of sugar by the peripheral

tissues has been brought forward by Drury [84] and endorsed by Mann [82 83] These authors have found that after hepatectomy the spontaneous fall of the blood sugar is faster, and the amount of sugar that must be infused to keep the blood sugar constant is greater, when the animals have previously received a diet rich in carbohydrate than when they have been starved This work has been denied by Soskin,[122] but it is doubtful if his preparations were suitable for investigation of the delicate variations in the peripheral uptake of sugar as a result of dietary changes It thus appears that conditions which diminish sensitivity to insulin also diminish the ability of the peripheral tissues to utilise the blood sugar

In the intact animal or human subject the only method available for studying the rate of removal of sugar by the peripheral tissues is to measure the difference between the sugar content of the arterial blood entering a limb and that of the venous blood leaving the limb [45] An increase in this A-V sugar difference indicates an increased rate of removal of sugar by the peripheral tissues A diminished A-V sugar difference is found in depancreatised dogs [46] and in human cases of diabetes mellitus,[82a] and this difference is restored to normal by injection of insulin In a normal subject the A V sugar difference in the resting state is small, but after ingestion of sugar the difference increases as the blood sugar rises, and then decreases to the fasting value as the blood sugar falls [50] This increase in the A-V sugar difference is attributed to the action of the pancreatic insulin secreted in response to the rise of blood sugar, and the effect of this pancreatic insulin in causing the peripheral tissues to remove the blood sugar can be measured by the area enclosed between the arterial and the venous blood sugar tolerance curves In fig 4 is shown an example of two experiments on the same healthy subject, in which after ingestion of a standard dose of glucose both capillary and venous blood sugar curves were estimated In one experiment the subject was taking a low carbohydrate diet, in the other a high carbohydrate diet The area enclosed between the capillary and venous blood sugar curves is the same in each case, indicating that the removal of sugar by the peripheral tissues was the same in both experiments But according to the results on hepatectomised animals the peripheral tissues should have removed less sugar from the blood when the subject was taking a low carbohydrate diet than when he was taking a high carbohydrate diet It has already been shown, however, that the removal of sugar from the blood increases as the head of pressure of sugar in the blood rises It thus appears that in the above experiments, when the low carbohydrate diet was being taken, the diminished ability of the peripheral tissues to remove sugar was compensated by the increased height to which the blood sugar rose, with the result that the action of the pancreatic insulin in promoting removal of sugar from the blood by the peripheral tissues remained the same as when the subject was taking a high carbohydrate diet The evidence thus points to insulin sensitivity being a phenomenon of the peripheral tissues and indicates that the purpose underlying the variations in the blood sugar tolerance curve resulting from dietary changes is to maintain relatively constant the supply of sugar to the peripheral tissues

So far as is known, the main consumption of sugar takes place in the extrahepatic tissues, and it might therefore be expected that, if insulin sensitivity is a phenomenon of these tissues, wide variations in insulin sensitivity would be associated with detectable variations in the oxidation of sugar The most important work in this field is that of Dann and Chambers [39] on the effect of starvation on the specific dynamic action of glucose When glucose is given orally to a dog, the increased oxidation of sugar is indicated by a rise both in the consumption of oxygen and in the respiratory quotient In dogs starved for three weeks this effect of glucose is greatly reduced At the time when this work was done it was generally accepted that starvation decreased the output of pancreatic insulin The work we have been considering, however, shows that it is the sensitivity to insulin

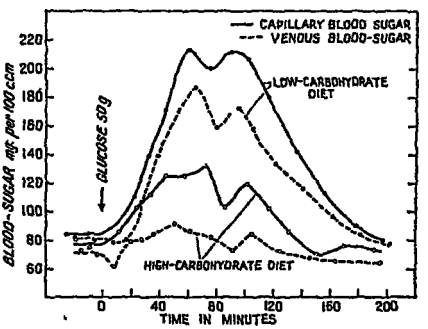

FIG 4—Two experiments in the same healthy subject, showing the rise of capillary blood-sugar and the rise of venous blood-sugar after ingestion of 50 g of glucose Before one experiment the subject was taking a low-carbohydrate diet, before the other a high carbohydrate diet The area enclosed between the capillary and venous blood sugar curves indicates the amount of sugar removed from the blood by the peripheral tissues The areas are approximately equal in both experiments [50]

which is decreased by starvation, and it is therefore significant that Dann and Chambers found that large doses of insulin did not restore to normal the ability of the starved dog to oxidise carbohydrate These workers showed, however, that the oxidation of glucose in dogs could be restored to normal in three or four days by repeated administration of glucose, a measure which increases the degree of sensitivity to insulin In man Baur [10] found that the consumption of oxygen by men receiving a low carbohydrate high fat diet was significantly lower than when they were taking a high carbohydrate low fat diet This finding has been confirmed, but it also appears that after ingestion of glucose the resulting rise in the respiratory quotient indicates that the proportion of the ingested glucose oxidised when taking either of the two diets is not greatly different [27] Thus restriction of carbohydrate coincidentally impairs insulin sensitivity and ability to oxidise glucose, whereas administration of carbohydrate restores both these properties When the sensitivity to insulin is moderately decreased, as by simple restriction of dietary carbohydrate, the coincidentally decreased ability to oxidise carbohydrate is compensated When, however, insulin sensitivity is much impaired, as by prolonged starvation, the compensation may be inadequate, and ingestion of glucose may not produce the full normal increase in metabolism

The importance of insulin sensitivity in carbohydrate metabolism is now apparent Decrease in

insulin sensitivity, if uncompensated, leads to diminished utilisation of sugar. To counteract this diminution of sugar utilisation the blood-sugar curve is elevated and the head of pressure of blood-sugar thereby increased. As a consequence of this increased head of blood-sugar pressure the action of the insulin secreted by the pancreas is facilitated. The impaired sensitivity to insulin is thus compensated, with the result that the rate of utilisation of sugar by the tissues is maintained within relatively normal limits (table II). This problem of insulin sensitivity has been considered in some detail because it provides an excellent example of the reaction of the body when its ability to utilise carbohydrate is impaired. These reactions take place in the healthy subject and cannot be considered abnormal. When we come to consider the diseases in which ability to utilise carbohydrate is impaired, we shall see that these same reactions are much in evidence. The thesis which I shall then be concerned to develop is that these reactions, particularly the hyperglycæmia of diabetes mellitus, are not abnormal processes, deleterious in themselves, but manifestations of an attempt to compensate the impaired ability of the tissues to utilise carbohydrate.

TABLE II—EFFECT OF CHANGE IN INSULIN SENSITIVITY

Insulin sensitivity	Effect	Compensation	Result
Diminished	(a) Insulin action impaired (b) Utilisation of sugar impaired	Increase in height of blood-sugar	Sugar utilisation approximately normal
Increased	(a) Insulin action increased (b) Utilisation of sugar increased	Decrease in height of blood-sugar	Sugar utilisation approximately normal

A NEW SERUM IN THE PASSIVE CONTROL OF SCARLET FEVER

BY D. B. BRADSHAW, M.B Dubl., D.P.H.
IMMUNOLOGICAL OFFICER AT THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, LONDON

IT is difficult to know how far one is justified in recognising scarlet fever as a disease per se rather than as one of the results of infection of the upper respiratory tract by certain strains of hæmolytic streptococci. That the latter view is fundamentally correct has long been apparent on clinical and epidemiological grounds, but conclusive proof was not forthcoming until the introduction by Griffith (1934) of the serological classification of the hæmolytic streptococci. The hæmolytic streptococci concerned are chiefly the many serological types which fall into Lancefield's group A and need not be further particularised here. The clinical condition caused by infection with such an organism depends partly on the site of the infection—e.g., upper respiratory tract, genital tract in the puerperium, and wounds—and partly on the immunological condition of the person infected. With an infection of the upper respiratory tract in the absence of circulating antibody to the erythema (Dick) toxin, scarlet fever develops; when the specific antibody is circulating in sufficient concentration the toxin is neutralised, the rash does not appear, and the diagnosis is tonsillitis, septic sore-throat, or the like. It follows that such infections or their complications—e.g., otitis media, rhinitis, and mastoiditis—may produce secondary cases of scarlet fever if transmitted to Dick-positive subjects. Similarly, hæmolytic streptococcal "colds," infected wounds, or discharges may be responsible for secondary cases of scarlet fever.

The rational method of classifying these infections is evidently bacteriological rather than clinical, as in enteric and pneumococcal infections. Administratively, however, scarlet fever is still an entity, since it is a notifiable disease, whereas its congeners (other than erysipelas and puerperal infections) are not. Moreover, in communities containing a relatively large proportion of Dick-positive reactors it is likely to be the most frequent manifestation of hæmolytic streptococcal infections of this type. Thus in the wards of a children's hospital, where commonly half or more of the patients are Dick-positive, scarlet fever constitutes the most striking evidence of the existence and spread of cross-infection with this group of organisms.

Like many other hospitals, the old Hospital for Sick Children admitted septic otorhinological cases to a general surgical ward. Such a ward offers considerable opportunity for cross-infection with hæmolytic streptococci (Okell and Elliott 1936) and is likely to present an undue number of cases of scarlet fever. By dint of careful barrier nursing the number of cases of scarlet fever was kept commendably low, the figures being —

1934	5 cases	1936 .. .	3 cases
1935 . .	9 „	1937 (1st half) ..	4 „

Pending the opening of new wards with adequate isolation accommodation, it was decided to administer scarlet-fever antitoxin prophylactically to all cases on admission to this ward, in an attempt to reduce still further the number of cases of scarlet fever.

EXPERIENCE WITH EARLIER SERUM

The successful routine use of a serum prophylactically on such a scale depends not only on its efficacy as a preventive but also on its liability to cause serum reactions. Although ad-hoc records had not been previously kept, the opinion was held at Great Ormond Street that the commercial scarlet-fever sera then in use at the hospital were reliable prophylactics but caused serum reactions in an undue proportion of patients. These reactions, although very rarely dangerous, were often severe and interfered with the well-being and treatment of the patients.

The proportion of patients exhibiting reactions after the injection of sera in general varies from one batch of serum to another, with individual sensitivity, but especially according to the amount of protein injected. The most recent published figures agree remarkably closely: 21·9 per cent. for diphtheria antitoxin (Davis 1938); 28·1 per cent. for diphtheria antitoxin and 22·7 per cent. for scarlet-fever antitoxin (Hunt 1932). At Great Ormond Street one had the impression that stock scarlet-fever antitoxin used in 5 c.cm. doses gave a substantially higher figure, some batches giving reactions in quite half the patients.

TECHNIQUE AND RESULTS WITH REFINED SERUM

It was therefore decided to give a trial to the scarlet-fever antitoxin introduced by Lederle Laboratories. According to the makers, these sera are refined and concentrated by a process of "selective and controlled digestion of the inactive, reaction-producing proteins by means of proteolytic enzymes."

The sera are said to contain the pseudoglobulin fraction only and are claimed to give a very low incidence of serum reactions The dosage recommended for passive protection against scarlet fever is 1–1 5 c cm (100,000 original neutralising units) Past experience with other sera suggested that this dosage was excessive for our purpose, for the patients at Great Ormond Street are all under twelve years of age Accordingly a routine dosage of 0 75 c cm. (75,000 original neutralising units) was employed Babies under four months of age were not injected, for they are usually Dick negative

Most patients received their serum within a few hours of admission and virtually all within twenty-four hours A few patients remaining in the ward for periods of only a few hours did not receive serum The serum was given intramuscularly in the deltoid region or thigh indifferently No distinction was made between patients receiving serum for the first time and those who had had serum on a previous occasion The ward sister and her nurses were instructed to report all disturbances, however slight, which might conceivably be referable to the administration of serum

The period during which serum was thus given as a routine was from July 27, 1937, to Aug 4, 1938 (just over a year), and 658 patients received the serum During the course of the trial 1 case of scarlet fever developed in the ward This case cannot be recorded as a failure of the serum to protect in that the child had been forty eight hours in the ward before the administration of serum and that signs of scarlet fever appeared within a few hours of the injection

The serum has also been employed in the control of scarlet fever in the general medical and surgical wards The method of dealing with scarlet fever in these wards has been (1) immediate removal of the primary case, (2) Dick testing of all contacts, and (3) the administration of Lederle serum 0 75 c cm to all positive reactors within twenty four hours of the diagnosis of the primary case During the period under review there have been 14 primary cases of scarlet fever in the general wards, involving 135 Dick positive contacts They were dealt with as above, and no secondary case developed

As is so often the case in human protection experiments, there is no means of estimating how many susceptibles did in fact make effective contact and therefore would have developed scarlet fever if not passively protected Obviously efforts were made to make the number as small as possible The results in the otorhinological ward, where no case of scarlet fever developed during the twelve months in which routine serum was given as against 3–9 cases in the previous years, are no doubt within the range of chance variation The results obtained in the general wards are certainly not open to this criticism

Less favourable results have been obtained by Dr McSweeney at the Cork Street Fever Hospital, Dublin He has had several failures to protect when using Lederle serum to control the introduction of scarlet fever to diphtheria wards The conditions in his series were less favourable in that they were cases "whose resistance was at a very low ebb, exposed to pretty intensive infection with hæmolytic streptococci" (McSweeney 1939) There is also the possibility that the serum may not be equally effective against every type of scarlatinal streptococcus

The number of patients recorded as showing serum reactions is 10 out of a total of 703 receiving serum—i e, 1 2 per cent In 2 of the cases the reaction was local only, in the remainder there were general reactions, usually with an urticarial type of rash It is probable that a few cases developed reactions after discharge from hospital, but, even when allowance is made for this source of error, the percentage of reactions is remarkably low, especially when it is remembered that no precautions were taken in reinjecting patients who had had serum previously

SUMMARY

A new scarlet fever antitoxin (Lederle Laboratories) has been tested as a means of passive prophylaxis in the wards of a children's hospital

Secondary cases were practically abolished during the year in which it was used

In prophylactic doses it gave rise to serum reactions in less than 2 per cent of cases

My thanks are due to the members of the honorary staff to whose cases these figures relate and to Dr D N Nabarro, director of the pathological department, for much help and advice The work was done during the tenancy of a grant from the Sir Halley Stewart Trust

IN a number of papers Collier (1938 and 1939a, b) and Collier and Fasoveld (1938), working in Java have reported on a spontaneous polyarthritis of rats which can be transmitted in series, but of which the ætiological agent has not been isolated A very similar condition was demonstrated to one of us in 1930 in Nigeria by Mr R S Marshall, M R C V S, whose observations have not yet been published A closely allied condition has been found in rats in our own laboratory and in the rat colonies of two other laboratories in London The object of the present communication is to show that the causal agent of this disease is a pleuropneumonia like organism

THE SPONTANEOUS DISEASE

The disease has been seen in pure-bred black and white rats and in albino rats of the Wistar strain The joints most commonly affected are the tibio tarsal and the radiocarpal; less frequently the inter tarsal or phalangeal joints are swollen In the spontaneous disease, it is not uncommon to see three or all four of the limbs involved The first signs of swelling of an affected joint are accompanied by a glistening appearance of the skin, which is smooth and pearl coloured Often these appearances are localised to one small nodule Later the whole region of the joint takes on a pink and even purplish tint and is slightly œdematous This condition may eventually subside, leaving some thickening round the

joint; or, while the joint is still swollen, the skin may ulcerate and the limb below the joint may be gnawed off by the rat. The skin can be easily stripped off affected joints in the early stages, showing in the case of the tibiotarsal joint a fusiform swelling, of a pearly colour. On cutting the swollen tissues, straw-coloured fluid may be liberated.

Attempts to transmit the disease were made by removing the skin from affected joints with aseptic precautions and grinding up the whole joint with sterile sand. Normal saline was then added to make an approximately 10 per cent suspension and, after centrifugation at 3000 r.p.m. for 10 minutes, the supernatant fluid was inoculated into the pad of the hind foot of half-grown rats in doses of 0·2 c.cm. The first symptoms appeared usually in the tibiotarsal joints, more rarely in one of the intertarsal joints, after an interval of 4–6 days. In very large rats the incubation period was as long as 10 days, while certain full-grown rats showed no symptoms of infection.

ISOLATION OF A PLEUROPNEUMONIA-LIKE ORGANISM

Smears from affected joints showed the presence of large numbers of polymorphonuclear leucocytes and on occasions bacteria. Histologically, in the early stages, there was infiltration round the joint with polymorphonuclear leucocytes and large mononuclear cells. Later, fibroblasts appeared and what suggested pannus formation was noted. Finally the joint cavity was invaded, with disappearance of articular cartilage and absorption and disorganisation of the epiphysis.

The first step in the attempted isolation of the causal agent was the filtration of the affected joint tissues. A 10 per cent. suspension having been centrifuged as before, the supernatant fluid was filtered through gradocol membranes with A.P.D. of 940 mμ, 790 mμ and 680 mμ under a pressure of 3 atmospheres of nitrogen. The filtrates were then inoculated in doses of 0·2 c.cm. into the pads of half-grown rats together with a small amount of sterile agar: cultured on ordinary bacteriological media the filtrates showed no growth. Six to eight days after inoculation the tibiotarsal joints of the rats began to swell and a week later the joints were very definitely affected. Attempts at culture were made from joints thus infected by filtrates. No growth was obtained on the more commonly employed bacteriological media, but when agar or broth containing about 20 per cent. of defibrinated rabbit blood was employed, or when joint fluid was spread on Kheneberger's "special medium," growth was obtained of an organism whose growth characteristics and morphology resembled those of other pleuropneumonia-like organisms, more especially the organism which we have termed L5 (Findlay et al. 1938).

These agar and broth cultures, with the addition of sterile agar, when injected into the pads of rats caused swelling of the tibiotarsal joints after an interval of 4–6 days, and the appearance of the same symptoms as are caused by the injection of a suspension of the affected tissues. Histologically, the experimental does not differ from the spontaneous disease. Polyarthritis may occur in the experimental disease. Thus in one instance a rat inoculated into the pad of the right hind foot developed an acute arthritis of the left knee-joint 16 days later. Injected intravenously in rats of 50 g. body-weight in doses of 0·5 c.cm. fluid cultures induce polyarthritis in 5–8 days.

The pleuropneumonia-like organism, which is provisionally termed L7, is present in affected joints for considerable periods. During the acute stage it can be obtained in small amounts from the heart blood, popliteal lymph-nodes and spleen. L7 has been cultivated on the chorio-allantoic membrane of the developing chick embryo and reinoculation of the infected membranes in the pads of rats causes typical arthritis. Intracerebral injection of cultures in rats as a rule causes no symptoms, but in one instance a rat was moribund 4 days after injection. The brain of this rat contained the organism which further observation shows may remain latent in the brain for considerable periods, certainly up to 21 days.

Attempts have been made to infect species other than the rat.

Injection of agar cultures of L7 in the knee-joint of pigs was without effect, while injection in the pad of the foot of rhesus and cercopithecus monkeys and of rabbits, voles, guineapigs and hedgehogs produced no rise of temperature and no swelling of the joints. Injection of either infected filtered material from the rat or cultures of L7, mixed with agar, into the pads of mice gave rise, however, to swelling of the tibiotarsal joint in 2–7 days: the swelling may persist for 5–6 weeks. Without the addition of agar, little or no reaction is produced in mice. In some mice injection of cultures into the pad causes also a gelatinous œdema of the subcutaneous tissues of the abdominal wall, followed by death. Cultures of L7 on agar have also been injected intracerebrally into mice and give rise in 2–7 days to a fatal condition, associated with weakness in the hind legs, hunched back, coarse tremor and a tendency to turn in circles with the tail as a fixed point. Not infrequently, the skin over the frontal region becomes thickened, indurated and the eyes may be closed by a sticky exudate. In the first passage only one or two mice may show symptoms, but repeated passage, especially with the addition of sterile agar, causes 60–80 per cent. of the mice to develop cerebral symptoms. Histologically no lesions are seen in the brain beyond a slight degree of meningitis.

Cultures inoculated intravenously or intraperitoneally in doses of 0·5 c.cm. cause death in a high percentage of animals. In those that survive for 48 hours pleural or peritoneal exudates and arthritis are common. Intranasal instillation causes pneumonia in 5–8 days.

Smears from the brains of inoculated mice show the presence of large numbers of polymorphonuclear leucocytes and of rings, granules and comma-shaped structures which we have learnt to associate with infection by pleuropneumonia-like organisms isolated by us from mice (Findlay et al. 1939). Similar bodies have been seen in rat brain inoculated with agar cultures, in the chorio-allantoic membrane of the chick embryo, and in blood-broth cultures 24 hours after inoculation. They exhibit certain morphological similarities to the parasite known as *Eperythrozoon coccoides* and found in the blood of splenectomised mice. Like them the bodies stain readily by Giemsa's method and give a positive Feulgen reaction for nucleic acid. It seems that all pleuropneumonia-like organisms require an adjuvant such as agar or cells to start infection, if injected into animals. Mettam and Ford (1939), adopting Daubney's method (1936), demonstrated this recently in experiments on cattle with pleuropneumonia itself, and previous observations (Findlay et al. 1938) have emphasised its importance in regard to pleuropneumonia-like organisms in rodents. Collier (1939b) was unable to produce polyarthritis in mice.

Collier (1939a) showed that the injection into rats of certain organic gold preparations, Aurodetoxin

and Solganal B, prevented the development of polyarthritis in rats we have now been able to confirm and extend his results with solganal B by showing that this compound prevents the development of arthritis in both rats and mice injected with cultures of the pleuropneumonia like organism L7 Solganal B and other organic gold compounds also have a very remarkable effect in preventing symptoms in mice injected intracerebrally with L4, L5 and L6, other pleuropneumonia like organisms isolated from rats and mice

RELATIONSHIP OF L7 TO OTHER PLEUROPNEUMONIA-LIKE ORGANISMS

During the past few years observations have shown that the group of pleuropneumonia like organisms is very widely distributed On the one hand, saprophytic agents such as those described by Laidlaw and Elford (1936) and Seiffert (1936 and 1937) in sewage, humus, earth and similar materials undoubtedly belong to this group, as do the agents responsible for pleuropneumonia in cattle and agalactia in sheep and goats Incidentally, it is of interest to note that arthritis is by no means uncommon in goats affected with agalactia According to Pigoury (1938) arthritis occurs in 10–20 per cent of these animals, coming on usually about a week after the beginning of the disease One joint alone is as a rule attacked, generally that between the radius and the carpus, more rarely the tibiofemoral or the tibio astragaloid joint The symptoms vary from simple stiffness to acute arthritis with complete functional incapacity Spontaneous cure usually takes place after one or two months, but in some cases ankylosis is complete Serous inflammation of the joints is occasionally described as a late symptom in pleuropneumonia of cattle

At least four different species of pleuropneumonia like organisms have been isolated from mice L1 obtained from mice and rats is associated with *Streptobacillus moniliformis* (cf Kligneberger 1936 and 1938) This organism may occasionally produce arthritis in mice L3 has been found in the lungs of rats suffering from "bronchopneumonia" (cf Klieneberger and Stebbben 1937) and has recently been isolated from the brain of an apparently healthy mouse L5 was isolated from the brains of mice showing curious nervous symptoms—rolling disease (Findlay et al 1938) a very similar organism was subsequently identified by Sabin (1938) as the causal agent of a similar condition in America In America, Sabin (1939) has also isolated a pleuropneumonia-like organism from the brain of an apparently normal mouse Both L5 and this latter organism may produce an arthritic condition in mice when injected intraperitoneally or intravenously in large doses In this country, Findlay et al (1939) have also obtained on numerous occasions from mouse brains a pleuropneumonia-like organism L6, which differs from L7 serologically and in its growth characteristics This organism is also capable of producing arthritis in about 30 per cent of mice In rats, Woglom and Warren (1938a and b) described a progenic condition which they at first regarded as due to a filtrable virus This has now been shown by Klieneberger (1939) and Woglom and Warren (1939) to be due to a pleuropneumonia like organism L4, which is quite distinct from the mouse pleuropneumonia like agents L1 can, however, be adapted to mouse brains Recently Swift and Brown (1939) claim to have isolated from exudates and skin nodes in rheumatic fever in man a pleuropneumonia like organism which they have been able to grow on the chorio-allantoic membrane of eggs and have also passaged in mice

Attempts have been made to compare L7, the organism isolated from rat polyarthritis, with other pleuropneumonia like organisms obtained from rodents When L5 and L6 are injected into the pads of rats no arthritis results and the symptoms on intracerebral injection in mice are different L4, injected into the pad of rats and mice, produces an arthritis indistinguishable from that caused by L7, but its pathogenicity for mouse brains is greater than that of L7, while smears from the brains of mice infected with L4, although revealing structures not unlike virus elementary bodies, have shown no rings similar to those produced by L5, L6 and L7 L4, however, produces the same infiltration of the skin of mice following intracerebral inoculation L7, injected subcutaneously into rats, causes no formation of pus as does L4 In its growth characteristics on solid media L7 resembles in certain respects L5, though it develops more slowly Mice immune to L5 and L6 can be infected with L7

Further work, however, is required to determine the exact relation of L7 to other pleuropneumonia like organisms of rodents L7 is killed after heating for 30 min at 50° C It passes gradocol membranes with A P D of 560 mμ and 440 mμ but not 300 mμ It can be preserved in 50 per cent glycerin saline for 22 days it resists freezing and drying and a 0·5 per cent solution of phenol for at least a week at 4° C The greater part of a suspension is sedimented after centrifugation at 15,000 r p m for two hours

DISCUSSION

The spontaneous infectious polyarthritis which we have described in rats in London appears to be identical with, or very closely related to, the condition observed by Collier (1938) in Batavia except that his condition was not transmissible to mice It also resembles the condition observed by Marshall in Nigeria, referred to above, in a stock of laboratory rats maintained there It would thus seem as if the disease were by no means rare, and of wide geographical distribution, although no mention of it is made by Jaffé (1931) The isolation from this spontaneous rat polyarthritis of a pleuropneumonia-like organism is at the present moment of considerable interest since Swift and Brown (1939) claim to have obtained a pleuropneumonia-like organism from two cases of human rheumatism The possible bearing of our observations on human rheumatic conditions is now being actively investigated The fact that a spontaneous infectious polyarthritis can be studied experimentally under laboratory conditions is likely to throw further light on the human disease In this connexion, chemotherapeutic experiments, which will shortly be published in full, are of special interest, for gold salts have long been employed empirically in the treatment of human arthritic infections and these salts appear to have a remarkable action on experimental infections with the pleuropneumonia like organisms of mice and rats The sulphonamide group of drugs on the other hand has no action on the polyarthritis of rats In the pleuropneumonia like organisms there appears to exist a group of agents many of which have a tendency to produce arthritis in various animal species

CONCLUSION

A pleuropneumonia like organism has been isolated in pure culture from a spontaneous polyarthritis in

the rat, and has been shown to be the causal agent of the disease.

We desire to thank Prof. S. P. Bedson, F.R.S., and Dr. Wilson Smith for generously placing material at our disposal.

BACTERIOSTATIC ACTION OF SULPHANILAMIDE IN VITRO

INFLUENCE OF FRACTIONS ISOLATED FROM HÆMOLYTIC STREPTOCOCCI

BY T. C. STAMP, M.B. Camb.

READER IN BACTERIOLOGY IN THE UNIVERSITY OF LONDON, AT THE BRITISH POSTGRADUATE MEDICAL SCHOOL

SINCE the introduction of the sulphanilamide group of drugs in the treatment of infections, their mode of action has been much discussed. There is little evidence that they act mainly by stimulating the defence mechanisms of the body (McIntosh and Whitby 1939). It seems rather that they produce their effect chiefly by direct action on the bacterial cells, possibly by preventing the development, or bringing about the destruction, of the surface immunising antigens upon which the capacity to resist the defence mechanisms of the host appears largely to depend. This suggestion is supported by the fact that the capsules of pneumococci growing in vivo in the presence of M. & B. 693 appear to undergo degeneration and in later stages are no longer demonstrable (Telling and Oliver 1938).

This phenomenon however, as McIntosh and Whitby have pointed out, may be merely part of the degenerative process accompanying death of the organisms in vivo and not necessarily due to direct action of the drug on the bacterial cell. The results of tests in vitro and in vivo indicate that the drugs do not produce their effect by simple germicidal action, since there is a short lag period before they become effective, during which the organisms may multiply at their normal rate, or there may even be an initial stimulation of growth (Colebrook, Buttle and O'Meara 1936, Finklestone-Sayliss, Paine and Patrick 1937). It seems rather that the main action of the drugs is bacteriostatic, preventing the organisms from multiplying to their normal extent, by interference with their metabolic activities. This, it is suggested, may be brought about by inactivation of certain enzyme systems responsible for the breakdown of complex proteins. Evidence in favour of this view has been brought forward by Lockwood (1938) who has shown that the inhibition of growth of hæmolytic streptococci in serum by sulphanilamide is greatly decreased if a small amount of peptone is present. He suggests that sulphanilamide prevents the organisms from breaking down the complex serum proteins, but they are still able to utilise the simpler breakdown products of protein, such as peptone, as nutritive material. Attempts to demonstrate a direct action of the drugs on the metabolic activity of certain bacteria have not yet met with success (Mellon and Bambas 1937, Barron and Jacobs 1937).

In the present paper this theory has been investigated further and attempts have been made to determine whether substances other than peptone are antibacteriostatic. In preliminary experiments, employing small inocula of a highly sulphanilamide-sensitive group C strain of hæmolytic streptococcus, it was found that in media such as heart broth or Hartley broth relatively large amounts of peptone (1 per cent. or more) were required to produce any marked antibacteriostatic effect and the same result was obtained by enriching the medium with similar amounts of glucose or serum. It was also found that the addition to the medium of relatively small amounts of heat-killed bacterial cells of the homologous strain enabled small numbers of organisms to grow in dilutions of sulphanilamide normally producing complete inhibition—an effect similar to that produced, according to Lockwood, by peptone in serum. It seemed that the two effects might be brought about in the same way—namely, by the provision of favourable nutritive material. There was a further possibility however that the killed bacterial cells might produce their effect by supplying a sufficient concentration of a necessary enzyme factor which enables the organism to overcome the inhibitory action of the sulphanilamide.

It appeared that an explanation might be forthcoming if it were found possible to isolate from the bacterial cells the substance responsible for their antibacteriostatic activity, and submit it to chemical analysis. Accordingly attempts have been made to fractionate the bacteria in various ways and to test each fraction separately for its ability to overcome the bacteriostatic action of sulphanilamide and M. & B. 693 in different media.

EXPERIMENTAL

Fractions have been obtained from two different strains of hæmolytic streptococci by methods similar to those employed in the isolation of immunising fractions from hæmolytic streptococci (Stamp and Hendry 1937), involving extraction with dilute acids and alkalis.

The method of testing for antibacteriostatic activity consisted in incorporating a standard amount of each fraction in a series of tubes of medium containing varying dilutions of sulphanilamide or M. & B. 693. Each series of tubes together with a control set containing no fraction was then inoculated with a standard number of viable organisms, incubated and observed daily for the development of turbidity. With a suitably small inoculum, a degree of turbidity equal to that of a control sulphanilamide-free culture developed in the control series in the higher dilutions of the drug, while the tubes with the lower dilutions remained permanently clear. A similar effect was obtained with sets of dilutions containing some of the fractions tested, while with other fractions maximal turbidity rapidly developed in all dilutions, indicating that the fractions possessed antibacterio-

static activity An approximate indication as to the relative activity of different fractions has been obtained by determining the smallest amount of each required to produce maximal growth in all dilutions in a given time Another method employed in estimating the activity of different fractions has been to carry out daily viable counts on organisms growing in the presence of the fractions in suitable concentrations of the drug This method has of necessity been used on occasions when whole blood has constituted the test medium, but apart from such cases appears to have no advantage over the other method, besides being much more laborious

MATERIAL AND METHODS

Strains of hæmolytic streptococci —Strain "S 34" isolated from bovine mastitis, belonging to the *sorbitol-positive*, trehalose-negative subgroup of group C, has been used in the majority of tests It has been found to be very sensitive to the action of sulphanilamide and M & B 693 in vitro, but is only relatively slightly affected by the drugs in vivo Strain "Richards" isolated from puerperal septicæmia, belonging to group A, type 3, has also been employed on a number of occasions It has been found to be less sensitive than 'S 34 to the action of the drugs in vitro, though more sensitive than other group A strains tested It is however strongly inhibited in vivo

Size of inoculum —Preliminary tests with each strain were carried out employing inocula of varying size, to determine the maximum number of organisms that would grow out in high dilutions of the drug in different media while remaining permanently inhibited in the lower dilutions The most suitable inoculum of both strains for producing this effect was found to be approximately 1000 viable organisms (from an 18 hour Hartley-broth culture) in 5 c cm of medium Larger inocula (100 000 organisms or more) tended to grow out in the lowest dilutions employed, though the appearance of turbidity might be delayed for 24–48 hours or longer

Media —Hartley broth or heart broth has been employed in nearly all experiments Hartley broth has been prepared in the usual way by the tryptic digestion of horse muscle, and different batches have been found to possess an amino-N content of between 0 07 and 0 1 per cent as estimated by Sörensen's method of formol titration The inhibitory action of the drugs has been found to be fairly constant in repeated tests with the same batch of medium, but varied much more from one batch to another particularly with Hartley broth With one or two batches of this medium it has been found impossible to obtain permanent inhibition of growth in high concentrations of the drugs, even when very small inocula were used, the organisms tending to grow out after four or five days' incubation Excessive autoclaving in the preparation of the medium appeared to favour this effect It did not however seem more liable to occur in batches giving particularly luxuriant growth It was found advisable to avoid using such batches in testing different fractions, since though an indication was obtained as to relative antibacteriostatic activity, the results were not as clear-cut as when batches allowing a greater degree of inhibition of growth were used

Whole defibrinated human and rabbit blood have also been used in some tests With these media also it has rarely been found possible to obtain permanent inhibition of growth and in such cases reliance has been placed on the acceleration in the rate of growth produced by different fractions in estimating antibacteriostatic activity

Preparation of sets of dilutions of the drugs —500 mg of sulphanilamide or M & B 693 has been sterilised by autoclaving and dissolved in 500 c cm of medium A series of twelve dilutions from 1/1000 to 1/5 000,000 has been made up in the medium in 200 c cm amounts with aseptic precautions and transferred to sets of sterile ¾ in tubes in 4 5 c cm quantities

Method of testing fractions —A standard amount of each fraction or other substance to be tested contained in 0 5 c cm of saline or extract, was added to 4 5 c cm of each of the dilutions of drug In addition one set of dilutions received an equal amount of saline as a control The final dilutions of drug in each case have therefore been slightly greater than those indicated in the tables All tubes were then inoculated with approximately 1000 organisms and after shaking were incubated at 37° C Tubes were shaken daily and observed for the development of turbidity In the tables which follow the results recorded on each day during the first week have been set down in separate columns (+ = the development of a degree of turbidity equal to that of a control tube containing no drug, ± = intermediate degrees of turbidity, − = no visible growth, or in tests of acid extracts a slight turbidity similar to that of uninoculated control tubes) It was found that growth rarely developed in any tube after the first week Cultures were therefore discarded after 10–14 days' incubation

Very occasionally contaminants developed in certain tubes Usually they were easily recognised from their atypical growth In doubtful cases, cultures were plated out

METHOD OF ISOLATION OF FRACTIONS

The material for fractionation was prepared by growing strain "S.34" or strain "Richards" in 100 litres of Hartley broth for 24 hours at 37° C The bacterial cells were allowed to sediment at 0° C, the bulk of the supernatant broth was siphoned off, and the organisms were centrifuged down A small quantity of the supernatant broth was filtered and set aside for testing along with the fractions The deposited cells were resuspended in 300 c cm of distilled water and shaken for three hours at 37° C They were then recentrifuged and the supernatant washings were also filtered and set aside for testing After one more washing in distilled water the cells were resuspended in 600 c cm of distilled water and divided into two portions To one portion 2N HCl was added to give a final concentration of approximately N/25 HCl To the other portion 2N NH_4OH was added to give the same concentration of NH_4OH Each suspension was shaken at 37° C overnight and then centrifuged until the supernatants were almost clear They were then passed through Chamberland L3 filters and the filtrates were neutralised to pH 7 At this pH the HCl extract formed a dense precipitate A part of this extract was set aside for testing and the remainder was divided into two fractions by centrifuging The clear supernatant was removed and the precipitate redissolved in dilute acid After one reprecipitation it was redissolved in dilute HCl and neutralised

The filtered NH_4OH extract remained water clear on neutralisation A dense precipitate formed, however, on adjusting the pH to 4–5. A portion of the crude neutralised extract was set aside for testing, and the remainder fractionated by precipitation in this way The pH4 precipitate was reprecipitated once from solution in dilute NaOH, then redissolved in dilute NaOH and neutralised The clear supernatant at pH 4 was neutralised All manipulations were carried out as far as possible with aseptic precautions In the majority of fractionations no attempt was made to isolate the fractions in a solid state A rough estimate of the total amount of dissolved organic material present in each solution was obtained by precipitating an aliquot part with 9 volumes of alcohol, drying and weighing the precipitate, and also, in some cases, by taking an aliquot part down to dryness in vacuo over phosphorus pentoxide and weighing allowance being made for the weight of NH_4Cl calculated to be present Each solution was then diluted with saline, so as to contain between 100–200 mg per 100 c cm of dissolved organic material The addition

TABLE I—EFFECT OF WATER-SOLUBLE, HCL-SOLUBLE AND NH_4OH-SOLUBLE FRACTIONS ON THE GROWTH OF STRAIN "S.34" IN HEART BROTH WITH VARYING CONCENTRATIONS OF SULPHANILAMIDE

Tubes observed daily during the first week for visible signs of growth and the results recorded in columns 1–7.

+ = growth complete
± = intermediate degrees of turbidity
− = no visible growth

of 0·5 c.cm. quantities of these solutions to 4·5 c.cm. of medium resulted in a final concentration of 10–20 mg. per 100 c.cm.

ANTIBACTERIOSTATIC ACTIVITY OF DIFFERENT FRACTIONS

An investigation has been carried out of the effect of these fractions isolated from strain "S.34" on the inhibition of growth of the homologous strain in heart broth containing sulphanilamide, and the results are shown in table I.

It will be seen that the crude NH_4OH extract exerted a marked antibacteriostatic effect on sulphanilamide, growth being complete in all dilutions of the drug after 72 hours. A similar effect was obtained with the pH4-supernatant fraction of the NH_4OH extract. None of the other fractions have produced a result appreciably different from that of the control and have failed to support growth in all dilutions below 1/250,000. Control tests showed that the effect obtained was not due to the presence of NH_4Cl in the active extract. It appeared therefore that a substance capable of neutralising the inhibitory action of sulphanilamide in vitro might be isolated from the bacterial cells by extraction with NH_4OH, but not with dilute HCl. This substance was not present in an appreciable amount in a filtrate of the culture nor in an aqueous extract, and was not precipitated from the NH_4OH extract at pH 4. Essentially similar results have been obtained with

* mg per 100 c cm

the active NH_4OH soluble fractions in Hartley broth containing varying dilutions of M & B 693

It was of interest to determine the concentration of the active fraction necessary to produce any effect and also whether it was possible to inactivate it by treatment with dilute HCl in order to account for the lack of activity of the HCl extract Another fractionation has therefore been carried out in the same way A portion of the crude NH_4OH soluble fraction was acidified to a concentration of N/10 HCl, allowed to stand overnight at 37° C, and then neutralised. This was tested in Hartley broth along with the other fractions including varying concentrations of the NH_4OH soluble pH4 supernatant fraction The batch of Hartley broth employed in this test permitted no growth of the standard inoculum in concentrations of the drug below 1/500,000 The results of this experiment are shown in table II It will be seen that the results obtained in the previous test have been confirmed. There is no indication that the activity of the crude NH_4OH extract was destroyed by treatment with N/10 HCl Further tests have confirmed this finding It seems likely therefore that the inactivity of the HCl extract is due to the fact that the active substance cannot be extracted from the bacterial cells by dilute acid. The NH_4OH-soluble pH4 supernatant fraction is shown to be active in this batch of medium in a concentration of 1–2 mg per 100 c cm, but produces no appreciable effect in a concentration of 0 1–0 2 mg

Varying concentrations of this active fraction have been tested in another batch of Hartley broth in which the inhibitory action of sulphanilamide was not as marked The effect of heat on the activity of the fraction has also been investigated by testing varying concentrations of the fraction previously heated at 100° C for ten minutes The results are shown in table III

It will be seen that in this batch of medium a concentration of the fraction as low as 0 01–0 02 mg per 100 c.cm had an appreciable anti inhibitory effect In this concentration, turbidity developed in all dilutions of the drug by the sixth day, while in the control series growth was permanently inhibited

in several of the higher concentrations Furthermore the activity of the fraction was not appreciably affected by heating, the heated and unheated fractions producing very similar results in all concentrations employed

Fractions have also been isolated from strain "Richards" in the way already described and tested in Hartley broth with varying concentrations of sulphanilamide. The results shown in table IV indicate that an active fraction similar to that obtained from "S 34" may be isolated from this strain also It was of interest to determine whether these fractions were capable of stimulating the growth in sulphanilamide of the heterologous as well as the homologous strain Accordingly the activity of both NH_4OH-soluble pH4-supernatant fractions was tested with each strain The results shown in table V indicate that the action of the fraction is non-specific, the growth of the homologous and heterologous strains being promoted to a similar extent by each fraction. Tests of the "Richards" active fraction were also carried out in heart broth, but gave less consistent results In certain batches of this medium a higher concentration of the active fractions than that normally employed appears to be required to produce an appreciable antibacteriostatic effect.

FRACTIONATION OF THE NH_4OH-SOLUBLE pH4-SUPERNATANT FRACTION OF "S 34"

An attempt was made to fractionate the active fraction further and to isolate it in a solid state

The washed bacterial cells from 120 litres of Hartley broth culture of "S 34" were repeatedly extracted overnight at 37° C. with N/25 NH_4OH. The first two extracts containing the great bulk of extractable material were centrifuged, pooled and adjusted to pH 4. *The pH4-precipitate, together with a residue* of bacterial cells, was centrifuged down, leaving 900 c cm. of clear supernatant. This filtered with ease through an L3 candle and was neutralised. To 600 c cm. of the filtrate was added 1200 c.cm. of absolute alcohol. After standing overnight at 0° C., the precipitate which formed was centrifuged down, washed with absolute alcohol and ether and dried *in vacuo over phosphorus pentoxide*. The yield of this "67 P" fraction was approximately 2 per cent. of the whole NH_4OH-soluble pH4-supernatant fraction It appeared to consist mainly of material similar to the pH4-precipitate fraction.

To the supernatant with two volumes of alcohol a further seven volumes or 4200 c.cm. of absolute

* mg per 100 c cm

alcohol were added After standing overnight at 0° C, the precipitate which formed was centrifuged down, washed and dried off as before The yield of this "90 P" fraction was found to be approximately 20 per cent of the total The supernatant with nine volumes of alcohol was then taken down to dryness in vacuo and drying was completed over P_2O_5 (phosphorus pentoxide) This '90 S" fraction was found to contain approximately one quarter of its weight of NH_4Cl The total concentration of dissolved material other than NH_4Cl present in the pH4 supernatant fraction of the NH_4OH extract was approximately 600 mg per 100 c cm This represents a yield of between 5–10 per cent of the total weight of the unfractionated cells as compared with a yield of 10–20 per cent of the pH4-precipitate fraction These yields are however only approximate and appear to vary considerably with different batches of cells

The three fractions— 67 P, "90 P, ' and "90 S"— isolated from the crude NH_4OH soluble pH4 supernatant fraction have been tested for anti-sulphanilamide activity in Hartley broth in the usual way, in a concentration of 10 mg per 100 c cm, the solutions of the fractions being heated to 100° C for ten minutes to sterilise before incorporating in the medium Tests of peptone and glucose added to the medium in ten times this concentration have also been included in this experiment The results are shown in table VI

It will be seen that in this batch of medium sulphanilamide had a very marked inhibitory effect, the standard inoculum of approximately 1000 organisms failing to grow out in any of the dilutions employed in the control series A similar effect was obtained in all the other sets of dilutions except the series containing the '90 S' fraction This fraction appears to be strongly antibacteriostatic and allowed the organisms to grow out by the fourth day in all dilutions of the drug

INFLUENCE OF PEPTONE AND OF "S 34" FRACTIONS ON GROWTH OF "RICHARDS" IN WHOLE BLOOD CONTAINING M & B 693

Experiments have been carried out to determine whether the fraction '90 S" is capable of antagonising the effect of the drugs in whole blood as well as in broth media Tests with both "Richards" and "S 34" strains have shown that even when very small inocula consisting of approximately 10 organisms were employed in rabbit or human defibrinated blood containing either drug in a concentration of 1/5000, the organism nearly always grew out after a lag period of a few days An indication as to the activity of different fractions under these conditions has been obtained by determining the degree to which the fractions were capable of reducing this lag period Different fractions in varying concentrations contained in 0 5 c cm of saline have been added to 4 5 c cm quantities of human defibrinated blood containing M & B 693 in a concentration of 1/10,000, and these have been inoculated with approximately 10 organisms Cultures containing peptone and controls consisting only of blood with and without the drug were also included in the test The rate of growth in each culture was estimated by daily viable counts, the rapid viable counting method described by Miles and Misra (1938) being employed, and the results are shown in fig 1 It will be seen that in this test the fraction "90 S" produced an appreciable acceleration in the rate of growth of the organisms in a concentration as low as 1/1,000 000 A similar effect was produced by peptone but only when considerably larger amounts were present The acid extract, as on previous occasions, was completely inactive The results therefore with whole blood, though not as clear cut as in the previous experiment with Hartley broth, tend to confirm the view that fraction "90 S" contains the active factor

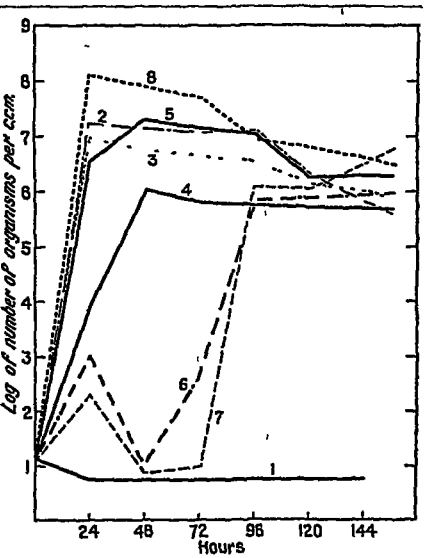

FIG 1—Showing the effect of different fractions isolated from streptococcus strain "S 34," and also of peptone, on the growth of strain "Richards" in defibrinated human blood containing M & B 693 in a concentration of 1 in 10,000

THE CHEMICAL PROPERTIES OF FRACTION "90 S"

By D BEALL, Ph D

This fraction is a hygroscopic amorphous yellow powder completely soluble in water After drying in vacuo nitrogen determinations were made by nesslerisation before and after Kjeldahl digestion, thus giving the ammonia nitrogen and total nitrogen of the samples The free amino acid content was determined by the colorimetric method of Folin Owing to the complexity of the mixture no attempt was made to obtain C and H figures but the ash content was estimated The amount of reducing sugar before and after acid hydrolysis was also found The figures obtained are given in table VII together with 'corrected values" on the assumption that all the ammonia nitrogen was present as ammonium chloride and also corrected for an ammonium chloride ash free basis

The combined reducing sugar was estimated by refluxing 28–36 mg samples for one hour with 5 c cm. N HCl exactly neutralising the excess acid with N NaOH and determining the liberated sugar by the Harding modification of the Schafer Hartmann method

FIG. 2—Method of isolation of fractions

In order to obtain further information about the form of the combined nitrogen, a number of qualitative tests were carried out using a 1 per cent. solution of the crude material It gave a positive xantho-proteic reaction and a very strong ninhydrin reaction. The modified Millon reaction (mercuric-nitrite test) and formaldehyde tryptophane reactions were negative. A negative biuret reaction was obtained even after allowing an N.NaOH solution to stand for

48 hours in a desiccator over sulphuric acid in order to remove the ammonia No precipitation occurred with trichloracetic acid, tannic acid, or sulphosalicylic acid. The Molisch reaction was positive.

DISCUSSION

The results of experiments recorded in this paper indicate that it is possible to isolate from broth cultures of hæmolytic streptococci a substance capable of antagonising the bacteriostatic action of sulphanilamide and M. & B. 693 in different media. The substance may be extracted from the bacterial cells by means of dilute NH_4OH, but is not removed in appreciable amounts by extraction with water or dilute HCl It is not precipitated from the ammoniacal extract on acidifying to a pH of 4–5, nor by the addition of nine volumes of alcohol (fig. 2) The activity of the substance is not affected by heating to 100° C and does not appear to be highly specific since it produces a growth-promoting effect in the presence of the drugs not only on the homologous strain but also on a strain belonging to a different serological group The substance is active in low concentrations, under favourable conditions exerting an appreciable effect in a dilution of 1 in a million, while a very marked effect has been obtained in nearly all experiments in a concentration of 1/10,000. A preliminary chemical analysis of the partially purified active substance indicates that it consists of material of relatively low molecular weight. It gives negative tests with various protein precipitants and also a negative biuret reaction A positive Molisch reaction and also estimations of the amount of reducing substance on hydrolysis show the presence of a small amount of carbohydrate material. A strongly positive ninhydrin reaction was obtained indicating the presence of free amino-acids The fraction also contains some 10 per cent of ash and about 25 per cent of NH_4Cl. It is evident that further purification and analysis of the active substance must be carried out before any definite indication can be obtained as to its real chemical nature and the way it produces its antibacteriostatic effect

There appear however to be several possible explanations of the results obtained in the present experiments, consistent with the view that the drugs exert an inhibitory influence on the activity of certain enzymes concerned in bacterial metabolism

In the first place the active fraction may contain a necessary nutritive factor, possibly an essential amino-acid, the production of which is interfered with by the action of the drugs This substance is unlikely to be one of the common simple amino-acids since a marked bacteriostatic effect can be obtained in a medium such as Hartley broth which contains a high concentration of these substances But it may be one of the rarer amino-acids which the organisms have to synthesise or even consist of a more complex molecule necessary for the synthesis of bacterial protein.

There is the further possibility that the active substance is an essential part of the enzyme system affected by the drugs It is unlikely that the activity of the fraction is due to the presence of the enzyme itself, since it is not affected by heating to 100° C nor by treatment with dilute acids and alkalis. It may be however that the activity of the drugs is

directed not against an actual enzyme but rather against a substance of the nature of a coenzyme upon the presence of which in many cases the activity of enzymes has been shown to be entirely dependent These substances are often relatively simple compounds of low molecular weight and are not infrequently resistant to treatment with heat, acids and alkalis The presence of such a substance in the active fraction might therefore be responsible for the effects produced It seems probable that the correct explanation of the antibacteriostatic activity of the fraction is to be found along these lines, but until further knowledge has been gained as to the chemical nature of the active factor it is impossible to give a definite answer to the problem

SUMMARY

1 A fraction capable of antagonising the bacteriostatic action of sulphanilamide and M & B 693 in vitro has been isolated from a broth culture of a group C haemolytic streptococcus

2 The fraction can be extracted from the bacterial cells by means of dilute NH_4OH but not with water or dilute HCl

3 The fraction is active in low concentrations and is resistant to heat, dilute acids and alkalis It appears to be non specific in its action

4 Preliminary chemical analysis indicates that the active fraction is free from protein and consists of a mixture of substances of relatively low molecular weight, including free amino acids

5 An apparently similar fraction has also been isolated from a culture of a group A haemolytic streptococcus

6 Possible ways in which this substance may produce its antibacteriostatic effect are discussed

I am greatly indebted to Dr D Beall who has very kindly carried out the chemical analysis on fraction "90 S" My thanks are also due to Mr F W Jelks for his invaluable technical assistance The general expenses connected with this investigation have been met by a specific grant from the Pilgrim Trust

DISTURBANCE of MEMORY AFTER CONVULSION TREATMENT

By GLOFFREY TOOTH, M B Camb
ASSISTANT MEDICAL OFFICER MAUDSLEY HOSPITAL (L C C), LONDON AND
J M BLACKBURN Ph D Camb, B Sc (Econ) Lond
LECTURER ON PHYSIOLOGY AT THE LONDON SCHOOL OF ECONOMICS

THE object of this paper is to report certain *undesirable effects* which have been noted after the administration of convulsants for the treatment of mental illness These effects may be described as "intellectual impairment," and were *observed* typically as defects in memory

The case material consists of a series of patients treated in the wards of the Maudsley Hospital during the six months March to August, 1938, most of these recovered and have been followed up to the present time The total number of cases treated during this period by the administration of the convulsants Cardiazol or Triazol was 37, but an accurate statistical survey of all these is unfortunately impossible, owing to the elimination of over half the number 6 patients left hospital after less than five injections, 6 patients did not improve or got clinically worse under treatment, and 9 patients were discharged without investigation of their intellectual capabilities by the detailed methods *presently to be mentioned* The remaining 16 patients, most of whom have been under the personal care of one of us (G T), formed the basis of the present investigation Of these, 12 were diagnosed as schizophrenic, and all but 1, who is still in hospital, improved sufficiently to return to work or household duties. Of the remaining 4 patients, 3 were *suffering from* depression of over eight months' duration, and 1 was in a severe obsessional state Of the depressives, 2 made considerable improvement and left hospital, 1 is still in hospital, complaining mainly of the memory defect to be discussed, and the obsessional is still attending in the outpatient department, only slightly improved. Table I gives a summary of the cases, diagnosis, treatment, and also results of the psychological investigation which is described in the latter part of the paper

TABLE I—SUMMARY OF CASES, TREATMENT, RESULTS AND MEMORY IMPAIRMENT

Case	Age	Diagnosis	Fits	Convulsant used	Average amount used (g.)	Result	Memory loss (noted)	Memory loss (tested)	Followed up
1	51	Dep	13	C	0·75	Rec	+++	+++	0
2	40	Schiz	13	C	0·62	Rec.	+++	+++	+

For purposes of comparison the doses of triazol have been given in terms of the equivalent quantity of cardiazol 0·01 g triazol being taken as equal to 0·5 g cardiazol C, cardiazol T, triazol I, insulin Dep depressive, Schiz schizophrenic, Obses, obsessional, Rec, recovered, I P inpatient at present, Imp, improved, ++++, certain impairment +++, almost certain impairment, ++, probable impairment +, possible impairment, 0, no impairment, N T, not tested

CASES ILLUSTRATING MEMORY LOSS

It will be seen from the table that of the 16 patients, 9 complained of memory difficulty The most striking

confirmation of this has come from the friends and relatives of the patients; in fact, attention was first drawn to the subject by the relatives of the second patient to be treated in hospital (no. 10, table I)

This patient developed an acute paranoid reaction, which progressed in hospital to a mixed schizophrenic state with catatonic features and a most florid symptomatology. After four weeks of treatment, consisting of ten convulsions, he lost most of his symptoms, and was able to go home for the weekend. There, according to his fiancée, he showed improvement, but seemed absent-minded, and had difficulty in recalling relatively unimportant matters connected with his daily life. Attention was first drawn to this deficiency on the second day, when, during conversation with some friends, he was unable to remember the name of the seaside resort where they had spent the previous afternoon. Questioning of the patient by his friends had revealed a number of other facts that he had forgotten, for instance, the name of the restaurant where they had lunched and what he had eaten; these facts were easily recalled once they had been mentioned. When last seen, eight months after treatment, he stated that it was still difficult to recall the names of people whom he had previously known quite well.

This patient also showed "lacunar amnesia," amounting to a retrograde amnesia, which covered the six weeks during which he had been most acutely ill, and the cardiazol injections had been started. This condition, which persisted for about three weeks, cleared up suddenly in three days. The amnesia can hardly be attributed to the treatment for the patient recovered from it in the course of treatment. Further, it was easily explicable on psychological grounds, as it was present at a stage of recovery when such unpleasant memories might well be suppressed.

Another case illustrating this memory difficulty is no. 5 in table I, a German refugee highly trained as a statistician and shorthand-typist. She had made a suicidal attempt during an acute paranoid psychosis, and when admitted to hospital was in a catatonic stupor. After eight convulsions induced with triazol, she made an apparently complete recovery from her attack, but started at once to complain that her memory, which had previously been exceptionally good, now played her tricks; on one occasion she was embarrassed by not being able to recall the name of a cousin whom she knew well, and who visited her in hospital. During the year preceding her illness she had learned English shorthand well enough to enable her to obtain a responsible secretarial post in this country. On recovery from her psychosis, five months after the onset, she had great difficulty in remembering this more recently acquired attainment. It had not, however, been completely forgotten, the defect involving only a certain number of signs which she had to relearn from the manual. In addition she showed some failure of retention: when she played tennis she could not retain the score during the game. This patient was discharged from hospital *ten weeks after the last injection* and has been interviewed three times in the six months since then. During this period, with characteristic German thoroughness, she retrained her memory by an elaborate system of self-imposed tasks, such as memorising and tabulating the contents of the shop windows of the town in which she was staying. When last seen she had obtained another position, and said that her memory gave her no more trouble Owing to her imperfect knowledge of English it was unfortunately impossible to assess the results of the standardised tests employing vocabulary on this patient

Another patient (no. 12, table I) came to the hospital for treatment of a rather insidious schizophrenia, which would ordinarily have been given a poor prognosis Treated with cardiazol, she had thirteen convulsions, and made considerable clinical improvement, but insisted on leaving rather than submit to further treatment. She has since been seen in the outpatient department. At the first visit, and subsequently, her husband complained more of her forgetfulness and impaired efficiency as a housewife than of her persisting psychotic symptoms, to which he was more accustomed. Before her illness this patient had been an obsessionally efficient housewife, but now she was always forgetting where she had put things, and complaining that she could not recall names and addresses of people whom she knew quite well Over a period of eight months since ceasing treatment her memory has improved both subjectively and objectively, but when last seen she said that she still had to use a list when shopping, as she could not yet rely on her memory.

Finally, no. 2 in table I is worthy of special note. This patient was admitted to hospital in what appeared to be a depressive state with obsessional features. During a period of two months under observation the purely affective side of her illness was to a large extent replaced by anxiety, and there were bizarre and fantastic delusions with auditory hallucinations In fact, the patient's condition at this time would qualify her for inclusion in the ill-defined group of "depressive states with schizophrenic features." Before the onset of her illness she had been a successful business woman; there had been no complaint of defective memory on admission, nor was this demonstrated in formal testing. Since the condition appeared to be stationary it was decided to use cardiazol, she was given thirteen convulsions and showed a fair degree of improvement. This patient, towards the end of her course of treatment (which she disliked intensely), had several episodes of acute excitement which came on twelve to twenty-four hours after the convulsion and which lasted from six to eight hours; during this time she was muddled and disorientated, and would do odd things, such as polishing the furniture with metal polish After recovery from each attack she would profess complete amnesia for the whole episode The treatment was finally discontinued at the patient's request, and she started almost at once to complain of memory difficulties Since these were, at first, mainly concerned with hospital matters, such as the names of patients and nurses, no great attention was paid to them. However, after her clinical state had almost returned to normal she found, when she was trying to pick up the threads of her business, that the names of customers and telephone numbers, which she had carried in her head for years, now eluded her Seen in the outpatient department over a period of eight months she said that this defect has gradually improved, but, on close questioning, it seems more probable that she has become able to compensate for a still existing deficiency. The test results bear out this impression

This patient further showed a very remarkable change . soon after the end of her treatment, when she came to interest herself in occupational therapy, she announced that she was no longer right- but left-handed. No great notice was taken of this statement at the time, as she was still far from well, but as she improved, it was found that she was using her left hand for things for which she had previously relied on her right. Now that she has been hard at work as a fur machinist for several months, she is gratified to find that she can get through a larger amount of work than formerly, as she is now ambidextrous. No neurological alterations were discovered to account for this phenomenon, the power in the right hand remaining unaffected It may be supposed that there had been some sinistrality before.

These brief records indicate the type of memory loss which may follow convulsant therapy. Such loss is not a typical accompaniment or sequel of either depressive or schizophrenic states, although patients recovering from a schizophrenic attack like those in a depressive illness may complain of difficulty

in concentration or may show retardation on testing (Weitbrecht 1938, Schmorl 1938) In our cases it was not present before treatment with convulsants There was no direct relationship between the severity of the psychosis and the degree of memory impairment noticed after treatment, nor was the age of the patient a significant factor The fact that these defects were in most cases noticed and reported by relatives before being complained of by the patient would seem to rule out the possibility of their being the result of suggestion As most cases in this series were given the same number of injections, it is not possible to say whether the number of convulsions affects the incidence of memory disturbances The quantity and type of convulsant used is unimportant from this point of view Not all the patients in the series complained of memory disability, and no impairment was demonstrable on testing in a certain number, thus shows that some patients were more liable than others to suffer damage after this type of treatment Possibly this difference is due to a relative inability of the vascular mechanism of some patients to withstand the sudden alterations in pressure caused by a convulsion The finer delimitation of this hypothetical group is being investigated

There is a similarity between the complaints of these patients and the memory disturbances that are so often seen after head injuries and in epileptics Disturbances of the Korsakow type described by Plattner (1938) as arising after cardiazol treatment were not observed in our group No human post-mortem material has as yet been reported on, but if lesions in the human brain are found, comparable to those observed in the brains of animals subjected to repeated cardiazol convulsions (Reitmann 1938, Dreszer and Scholz 1939), the existence of some organic intellectual impairment would not be at all surprising

DESCRIPTION OF TESTS

The test employed was a modification of the Babcock test for mental deterioration (Babcock 1930) It is based on the assumption that a person's mental level indicated by a vocabulary test is likely to be little affected by organic impairment, whereas his mental level indicated by tests which require the application and organisation of knowledge to meet relatively new situations may be greatly lessened When, therefore, there is a large discrepancy between his score in the two types of test, the vocabulary being, let us say, that of the normal adult, while the average mental level on the other tests is that of the normal child of eight, organic impairment is indicated whereas if he obtains the score of a normal child of eight on both the vocabulary and the other tests, original defect is indicated The test has, in fact, been used by Babcock and others in differentiating between mental deterioration and mental defect

Subsequent work (Simmins 1933, Wittman 1933) has confirmed the validity of the vocabulary score as an indicator of original mental level, except in very severe cases of organic impairment

When the test is given to schizophrenic and to manic depressive patients, very little difference is found between the patients' scores on the vocabulary and on the other tests The picture is hardly different from that of the normal person The test, therefore, cannot be used to differentiate between "functional" psychosis and normality Its main use appears to be as a relatively specific indicator of the presence of organic impairment, differentiating it on the one hand from original defect, and on the other from normality and functional psychosis

Confirmatory work has been presented by Gilbert (1935), who compared the scores of 185 people in the twenties with those of 175 people in the sixties The average score of the younger group on the vocabulary and on the other tests was identical, whereas that of the older group showed a difference of nearly five mental years in favour of the vocabulary test Furthermore, Gilbert found that within the sixty-year-old group there was a significant difference between the scores of those under and of those over sixty five, the difference being less in the younger patients, and pointing to a progressive deterioration within the decade

The Babcock test, which was devised in America, is presented as a "battery"—that is to say, each test within the battery has been standardised independently of the others over a wide range of mental ages It is not therefore necessary, when presenting the test, to use every item in the battery Clearly, the more items one uses the more reliable will be the final average score, but some of the tests require a reconstruction (and a consequent restandardisation) before they are used on English people The fact that each item has been independently standardised, however, enables one to dispense with these Furthermore, some patients get tired or otherwise less coöperative after about three quarters of an hour's testing Consequently, in the experiment about to be reported, only the following tests out of the battery were used —

1 Vocabulary	9 Digits reversed.
2 Days of the week (T)	10 Knox cubes
3 Months of the year (T)	11 Days of the week reversed (T)
4 Alphabet (T)	12 Months of the year reversed (T)
5 Digits forward	13 Memory for designs
6 Counting backwards from 20 to 1 (T)	14 Memory for sentences
7 Immediate memory for a paragraph	15 Giving opposites of words (T)
8 Woodworth Wells sub stitution test (T)	

Tests marked (T) are scored on a time basis

A further modification of Babcock's procedure was also employed The rote tests numbered 2, 3, and 4 are tests of original knowledge rather than of application of knowledge to new situations The average mental level in these three tests was therefore combined with the level in the vocabulary test, and the average of the two groups was taken as representing the original mental level. The average score on the remaining eleven tests was then compared with this

If, for example, a patient had a mental level of 17 years on the vocabulary test, and of 18, 18, and 16 years on the three rote tests numbered 2, 3, and 4 respectively, the average level on the rote tests was 17⅓ years This was combined with the level on the vocabulary test, and the average was then taken, giving a mental level of a fraction over 17 years This figure was taken as representing the patient's original mental level It will be seen that the procedure gives a greater value to the vocabulary test than to any single rote test The vocabulary test is, in fact, regarded as being of equal value to the three rote tests combined In this way the emphasis on the vocabulary test as an indicator of original mental level remains, but instead of having to depend entirely on this single measure one can add to its reliability by combining it with the average score on three other tests of early acquired knowledge

An additional advantage of this modification of Babcock's procedure was that some tests scored on a

time basis were included in the tests of original level. This helped to differentiate cases of simple retardation from those showing impairment, for in this modification timed and untimed tests appear both in the indicators of original level and in the indicators of present level.

In the results shown in tables II and III a comparison is made between the scores on the modified Babcock test, as described above, of four groups of patients:—

(1) Schizophrenics who recovered without insulin or cardiazol treatment.
(2) Treated general paralytics
(3) Epileptics (taken off sedative drugs for one week before testing).
(4) Patients treated with triazol or cardiazol.

No impairment was assumed when there was a difference of only 2 years or less between the tests

TABLE II—RESULT OF MODIFIED BABCOCK TEST BEFORE AND AFTER CONVULSION TREATMENT

—	Number in group	Original level (years)	Present level (years)	Result
Recovered schizophrenics	7	17½	16	No impairment
General paralytics	7	16	13	Impairment
Epileptics	9	12	8	Impairment
Cardiazol-treated patients	12	16½	13	Impairment

TABLE III—NUMBER OF PATIENTS IN EACH GROUP WHO SHOW IMPAIRMENT—I.E., THREE OR MORE YEARS' DIFFERENCE BETWEEN THE TWO GROUPS OF TESTS

—	No impairment	Impairment
Recovered schizophrenics ..	6	1
General paralytics	3	4
Epileptics	3	6
Cardiazol-treated patients ..	5	7

of original mental level and those of present mental level. A discrepancy of this order was regarded as lying within the margin of error of the test. If the difference was between 2 and 3 years, however, impairment was regarded as possible; if between 3 and 4 years, impairment was taken as probable; if between 4 and 5 years, impairment was almost certain; and if over 5 years, the impairment was regarded as quite certain.

The numbers are small, but the tables agree in showing similarity between the general paralytic, epileptic, and cardiazol-treated groups, and a difference between these three groups and that of the spontaneously recovered schizophrenics.

RETESTING THE CARDIAZOL-TREATED PATIENTS

Of the cardiazol-treated patients, 7 were retested with the same test between three and seven months after their treatment had been completed, and 4 then showed less impairment or no impairment at all. The other 3, however, showed as much impairment on the retest as they had on the earlier test, performed soon after their treatment had been completed. In 1 of these 3 cases the retest was given as much as seven months after the treatment had been completed, in the second it was given six months after, and in the third, four months after completion.

It may be noted that the same test was given on both occasions. If there were any practice effect it would tend to lower the degree of impairment indicated by the retest. The fact that 3 of the patients continued to show impairment on retesting is therefore the more significant. It would be improper to conclude that the damage is permanent, but the evidence shows that it is not evanescent or negligible.

SUMMARY AND CONCLUSIONS

Of 16 cases treated with convulsants—comprising 12 schizophrenics, 3 depressives and 1 obsessional—13 recovered and 3 improved. Of these, 9 complained of memory difficulties which they maintained were due to the treatment and which in 5 cases were still present six months after cessation of treatment. A test confirmed the impression of organic intellectual impairment in 8 of the patients, though 2 of these did not complain of any disability. Susceptibility to the effects of convulsions seems to vary, for 3 patients did not complain of impaired memory, nor did they show impairment on testing.

Although the implications of this work are rather grave, it is doubtful whether they out-balance the value of the treatment in selected cases. The risk of memory impairment suggests however that convulsants should not be employed, except as an extreme measure, in patients whose livelihood depends on their memory and purely intellectual capabilities

We wish to express our thanks to Prof. Edward Mapother for permission to work with patients under his care, and to Dr. A. J. Lewis for his criticisms and suggestions. One of us (J. M. B.) is indebted to the Medical Research Council for a part-time personal grant which enabled him to undertake this work.

PAGET'S QUIET NECROSIS

BY J. C. R HINDENACH, M.D.N.Z., F.R.C.S.
ORTHOPÆDIC CHIEF ASSISTANT AND REGISTRAR AT ST GEORGE'S HOSPITAL, LONDON

THE term "Paget's quiet necrosis," denoting a particular morbid process, has now almost passed from the realm of current usage Despite this, its description persists in modern surgical textbooks, and occasionally a candidate in a viva-voce examination is asked for his knowledge on the subject How far surgical authors have strayed from Paget's original description will be seen in the extracts selected from four modern and reputable volumes Though the subject is not of vast importance, an attempted clarification may be of help.

Paget's original lecture was given in *1869* before the Clinical Society of London and published in the *Transactions* in 1870. He described the condition of a female, aged 19, who had had pain in her knee for one month. There was an oval swelling about 6 in. long nearly surrounding the middle of the shaft of the femur. Hard pressure over the swelling was painful. Otherwise the shaft appeared healthy The patient was in the habit of breaking thick pieces of wood across her thigh. At no time was there any sign of fever. Operation was decided on, and a 6 in. incision was made over the outer part of the

thigh All the tissues down to the periosteum appeared perfectly healthy

"The periosteum was, in the portion, divided ½ to ¾ in thick and in all its thickness, dense, tough, white and moderately vascular Between the periosteum and the bone, the incision had laid open a flattened irregular cavity from which a little blood coloured fluid escaped, and was followed by the protrusion of some soft substance like coarse granulations *In this cavity which was from* ½ *to* 1½ *in* in diameter, was a thin rough sequestrum separated from the wall of the femur, about 1½ in long and ¼ in wide The walls of the cavity of which the outer was formed by the thickened periosteum and the inner by the hollowed out surface of the femur, felt smooth and velvety, as if covered by granulations, like those of ordinary cavities containing sequestra The sequestrum appeared to be divided, not from the outermost layers of the femur, but from layers just within them"

Paget's comment on the lesion is as follows "The central point of interest is I think, in the fact of necrosis leading to separation of a bone, being unattended with inflammation of any of the features external to the periosteum, and with no more than a scarcely discernible amount of suppuration around the sequestrum"

Lawford Knaggs makes the following points about the process —

(1) The sequestrum lies in a cavity surrounded by granulations but with a puzzling absence of suppuration

(2) The sequestrum appears to be derived from the layers just within the outer surface of the bone

(3) Both inner and outer surfaces of the sequestrum are eroded

(4) Separation of the sequestrum may not be complete at the ends

(5) The process may be extending at the extremities while the bulk of the sequestrum has separated

(6) The initial lesion is probably a mild staphylococcal periostitis which becomes limited

Paget's quiet necrosis is, therefore, a process of local necrosis and sequestrum formation in the superficial layers of the shaft of a long bone The lesion is chronic from the beginning and affects mainly young adults There is a minimal amount of suppuration surrounding the sequestrum, and sinuses are not formed It is probably the result of a chronic osteitis due to a rather non virulent staphylococcus

In 1875 Paget, unfortunately, complicated the picture by his essay on Quiet Necrosis, published in his book "Clinical Lectures and Essays" in which he described again his original case and commented on two similar cases He then suggested that by a similar process of 'quiet necrosis" the formation of some of the loose bodies in joints might be explained He wrote that some loose bodies "are portions of the proper articular cartilage with or without some adjacent bone, which have suffered a 'quiet necrosis,' and been exfoliated into the cavity of the joint" He suggested trauma as the primary factor, and that the portion of bone was killed by violence and exfoliated without suppuration

It is most probable that the lesion he was describing here was that now known as osteochondritis dissecans Separation takes place into the joint without suppuration, but the loose body is not a true sequestrum, because it lives We have not in the aetiology of the lesion, advanced very far beyond Paget's original suggestion that trauma was a factor

The following extracts from four modern surgical textbooks show the lack of unanimity of the authors and the confusion which may be caused in the mind of the reader

(1) After a description of the late results of trauma to a joint with infection resulting in acute suppurative arthritis, "Articular cartilage tends to total destruction from ingrowth of pannus, from autolysis by the toxins in the joint and, once the underlying bone is exposed, by stripping off in flakes Portions of the bone may die and form sequestra (Paget's Quiet Necrosis) whilst new bone is thrown out in other places"

(2) "Necrosis results from the following conditions (*a*) (*b*). (*b*) a variety, described by Sir James Paget under the name of quiet necrosis occurs as a result of direct injury, the sequestrum separating without suppuration It is one of the causes of loose bodies in joints and especially in the knee, following a blow on one of the condyles"

(3) Quiet necrosis "was described by Paget as a process of local necrosis and sequestrum formation of a chronic character occurring in young adults *It is probable that his cases* were examples of chronic osteomyelitis due to a rather non-virulent staphylococcus The pathological process of exfoliation of outgrowths of synovial fringes and cartilage into joints he considered similar but the two conditions appear to be in no way similar"

(4) "*Certain inflammatory bone formations may closely resemble osseous tumours although in the circumstances, the more diffuse character of the enlargement is likely to resemble an ossifying sarcoma* rather than a simple osteoma In this connexion the extraordinary deposit of new bone which may gradually occur round a small sequestrum is of great practical importance To this condition Paget applied the graphic name of 'quiet necrosis'"

The reader may judge the above extracts for himself in the light of Paget's original descriptions

SUMMARY

(1) Paget's quiet necrosis is a process, not a disease The process is one of local necrosis and sequestrum formation associated possibly with a traumatic factor

(2) According to his original description the process took place in the superficial layers of the shaft of a long bone of a young adult

(3) Suppuration is minimal, and sinuses are not formed

(4) Paget later suggested that by the same process a portion of articular cartilage might be exfoliated into a joint and produce a loose body This probably corresponds to the lesion which we now call osteochondritis dissecans

---

"Be an anthropologist, Reeves Fish up a lot of facts, alleged on very doubtful authority, about primitive man—his marriage ceremonies, his burial customs, his system of land tenure Look at the whole mass of facts squint-eyed until you can see a theory in it Embrace the theory, trot out all the facts which support your theory, write a long appendix on all the facts which contradict your theory, showing them to be insignificant or irrelevant, and there you are

"Is there any money in it?

"No If you're out for that, I should take to psycho analysis The system's the same, generally speaking, only *instead of dealing with primitive man, whom* you can disregard because he isn't there, you are dealing with a living man, who will probably tell you that you are a liar Then you tell him that he is losing his temper, which is the sign of a strong inhibition somewhere, and that's just what you were saying all along The beauty of psycho analysis is that it's 'Heads I win-and tails you lose' In medicine your diagnosis of fever is a trifle disconcerted if the patient's temperature is subnormal In psycho analysis you say, 'Ah, that just proves what I was saying'"—HOWARD A KNOX, 'The Viaduct Si (London, 1939)

MEDICAL SOCIETIES

MEDICO-LEGAL SOCIETY

AT a meeting of this society on June 22, with Dr. G. ROCHE LYNCH, the president, in the chair, a discussion on

The Psychiatric Handling of Delinquents

was opened by Dr DENIS CARROLL He said that psychiatric advice should not be given without a careful study of the offender under suitable conditions. The selection in court of suitable offenders for investigation was difficult even for a psychiatrist. The presence of a psychiatrist in court, and more systematic instruction of magistrates and probation officers, offered a possible solution It would not be practicable to employ a psychiatrist in every court, and, generally speaking, the selection must be made at once, as not all offenders could be remanded. As research indicated the necessary diagnostic criteria it might be possible to mark certain obvious types of offenders as worth routine remand, so that the probation officer might obtain data to define the need for medical investigation. Some groups might even be found worthy of routine medical examination—e g , drug-addicts, young chronic alcoholics and some sexual offenders The provision of the Criminal Justice Bill which allowed the question of the mental treatment of an offender on probation to be raised at any time during the first three months of the period might provide a solution in many cases.

Dr. Carroll described the psychiatric investigation, which is usually carried out by a team consisting of psychiatrists, psychologists and specially trained social workers The psychiatrist conducts a full mental examination, and either he or a general physician examines the offender physically. The psychologist, often a non-medical expert, estimates intelligence and ability for certain types of work by a carefully constructed set of tests The social worker obtains a full history of the offender's past life, environment, family and other circumstances, visiting the relatives and friends Dr. Carroll said that much of this work could be done by the probation officer if properly trained, but he would find it difficult to give the necessary time The ideal is to employ a social worker who has been a probation officer An hour each for the doctor and psychologist and two hours for the social worker is usually long enough There is serious lack of provision for inpatient observation , special centres, both official and non-official, are required The bill will help by empowering the local authorities to set up, or subscribe to voluntary bodies setting up, certain types of observation and treatment centres Some offenders object to repeated visits for investigation, and difficulties arise when the offender has to be accompanied to the clinic In practice these difficulties are handled successfully by obvious modifications of the investigation and by tact. Some of the difficulties would be eased if the non-attenders and objectors were remanded in custody or for inpatient observation, but it is not always possible to know when troubles will arise. They are usually due to the deep-seated hostile or persecutory attitude of mind characteristic of certain types of delinquents

After the investigation a report is sent to the court embodying the important findings, explaining their relation to the offence, and suggesting what should be done by way of treatment—where it could be carried out, the need for supervision, and so on If possible some forecast of the future is included. The general treatment is that of the causes, which are multiple and can be grouped under the heads of clinical, sociological and psychopathological The clinical state includes such factors as organic or mental disease, the degree of intelligence, pathological personalities, emotional stress, and habit of crime Sociological factors include bad or broken homes, bad companions, unsuitable work or occupation, economic stress and temptation. They are apt to be given too much importance, for they produce delinquent behaviour only in a person otherwise predisposed Psychopathology includes all the underlying mental processes, some of which may produce delinquent behaviour in so-called normal types The various theories can be turned to direct account in prescribing and carrying out useful treatment Many of the mental mechanisms prescribed by the freudian school are widely used by non-freudian psychiatrists in treating delinquents Psychoanalysis of offenders should be carried out only by trained analysts, and the theoretical teaching of the various schools of thought should be applied only to those cases where it is known to be of value.

When advising or supervising sociological measures, Dr. Carroll continued, the psychiatrist should bear in mind any contributory factor the persistence of which is likely to result in further delinquency. Several methods may have to be employed at the same time and several people may be involved, and it is highly important to maintain contact between them. A good social worker is invaluable and can carry out much of the necessary treatment of parents and others Treatment must be adequate, and training or supervision must be thought of in terms of years rather than months. It is important to obtain full knowledge about any place to which the offender is sent, for success depends largely on the personnel of the institution or foster-parent Training implies general character training and the development of a sense of social responsibility, as well as training in some form of employment Of psychological methods, suggestion is of more use with juvenile offenders than with adults Re-education is especially valuable in milder personality deviations Some workers favour moral education, especially for normal offenders Persuasion is a useful weapon with the intelligent and weak type Probation work is very encouraging ; there is no difficulty in combining it with other methods, even intensive psychotherapy. The criterion of whether psychotherapy should be used is whether the emotional state which has developed calls for such special skill to resolve it

The outlook for people who have committed isolated or accidental offences is good unless they are clumsily handled, but a delinquent habit is very difficult to eradicate. The younger the offender the better the prospect The environment may be so bad that nothing short of segregation is any use The attitude of the offender to society is always a mixture of friendly and unfriendly feeling, and the greater the capacity for forming positive transferences to the outside world the better the prognosis The effect of punishment is not easy to forecast. In some types it is disastrous, and the serious juvenile offender is generally better treated without it. There is scope for the application of common sense. Many cases can be dealt with simply and rapidly, but the psychiatrist does not often see these—a tribute to those who select his cases

DISCUSSION

Dr NORWOOD EAST said that of 2311 offenders placed on probation within his knowledge, 70 per cent did not commit an indictable offence in the next three years Of 438 persons who had already committed an offence when placed on probation, 54 per cent did not commit a further offence for three years In about 70 per cent of cases ordinary penal methods contributed to success—a far better result than any claimed by psychotherapy Petty-sessional courts heard about 90 per cent of all charges in this country crime is not a menace but merely a nuisance Psychiatric treatment includes general medical treatment, and much can be done by diet and drugs, occupation and good companionship, and regulation of the daily routine There is nothing to hinder the prisoner from receiving necessary psycho therapy from the prison medical officer Most sexual offenders have a fixed habit of delinquency and are unwilling to be reformed Nevertheless, even if psychiatric treatment is not successful it may be useful in providing data for research into the fundamental basis of crime, especially of abnormal crime In adult cases investigation is more useful than treatment

Dr ALEXANDER BALDIE complained that psycho therapists are in some quarters rather improperly regarded as mystics and supernaturals The "court psychiatrist" does not yet exist A psychiatric observer or assessor, he said, would be of the greatest value not only to the court, but also to the hard worked prison officer and to others who are dealing with the disposal as well as the treatment of the offender It is deplorable that in the London courts, the stipendiaries of which are unequalled for their competence, so many offenders with pronounced psychopathic traits should go through the machinery of trial and disposal with their condition unrecognised through lack of means to bring it to the court's attention It would greatly assist the court in determining factors mitigating the offence if these psychopathic traits could be recognised

Dr J C M MATHESON declared that on the evidence of the figures the problem is not so great as might at first sight appear He doubted whether psychiatrists have passed the student stage and are yet able to recommend treatment for delinquency Perhaps the present suggestions are to a certain extent tentative The public should be told that very little is yet known, and that psychiatrists are still groping their way Progress would better be made by approaching the problem as students rather than as therapists The psychiatric adviser to the court might usefully bring to the court's notice certain abnormal features in persons charged

REVIEWS AND NOTICES OF BOOKS

The Englishman's Food

Five Centuries of English Diet By J C DRUMMOND, D Sc Lond professor of biochemistry, University College, London, and ANNE WILBRAHAM London Jonathan Cape 1939 Pp 571 12s 6d

THIS well printed and illustrated book makes fine confused feeding, as Dr Johnson is reputed to have said of the haggis It is a book more to be dipped into or browsed on than read straight through—it would make a fine bedside book for a dietitian The authors have spread their net wide and taken in poetry, political pamphlets, medical treatises, diaries, estate accounts, novels, herbals, and books on husbandry and gardening in their quest for evidence of what England has eaten down the ages The study is fascinating, though the reader may at times weary of the digressions and the sudden jump from topic to topic and from century to century The book would have been better if it could have been compressed and kept more chronological None the less it will be a rich delving ground for all interested in dietetics for years to come

The authors bring out how surprisingly slowly new foods make their way into a country, although no Elizabethan would recognise half the foods that we eat today The medieval garden had no fruits but apples, cherries and plums, if we except the grape of the monastic vineyard, and few vegetables except garlic, onion and leek. Fruits were not thought wholesome till 1750 Potatoes were introduced in late Elizabethan days but medical opinion was against them, and they did not appear in books on gardening till 1726 and were not taken up by the Board of Agriculture till 1700 Bananas were actually introduced into this country in the eighteenth century but were not a common article of food till the beginning of the twentieth Why then were deficiency diseases not rife? The answer is that they were Scurvy was a common disease in spite though by 1597 cresses and lemons were [illegible] as specifics, and Culpeper says that parsley and strawberries are "good to fasten loose teeth" There is evidence that vitamin A was deficient, for night-blindness and stone in the kidney and bladder were common Rickets too was rife in the Low Countries and North Germany in the fifteenth century, and sixteenth century painters showed the holy infant as a rickety baby

We see here what a debt this country owes to religious and political refugees in the importation of new foods, particularly from Holland. Royal marriages acted in the same direction. On the other hand, snobbery, or the desire to imitate the upper classes, militated as it still does against the adoption or retention of a sound diet. The last two chapters, called "The War" and "A New Era," will stimulate those who think nutrition the foundation of the national health to press forward their demands for a consistent and progressive Government food policy both in war and peace In five centuries our food has made great advances, but it is by no means satisfactory yet If this book shakes the complacency of the [illegible] proportion of the higher ranks of administrative officials" it will have done good.

"every gradation from absolute certainty through practical assurance down to faint possibility."

Dr. Spicer of Minnesota set out to study the literature of the traumatic factor in disease, a subject which he thinks has been rather neglected in the standard textbooks, and he presents a formidable bibliography, but he shows an indifferent critical faculty in extracting his material. In fact, he seems to have sought authority for asserting that almost every imaginable disease may be due to, or at least aggravated by, injury. The case-histories he quotes are often interesting but their evidential value is sometimes flimsy in the extreme For instance, a man sustained an electric shock, after which "the nurse . . . states . . . that the pulse was markedly irregular and rapid. The man apparently made a complete recovery." On this evidence Dr. Spicer concludes that electric shock may cause auricular fibrillation.

This mass of material was not collected without great industry on the part of the author, and it seems a pity that more discrimination was not used in its presentation.

Crystalline Enzymes

The Chemistry of Pepsin, Trypsin and Bacteriophage. By JOHN H. NORTHROP, member of the Rockefeller Institute for Medical Research. New York: Columbia University Press. 1939. Pp. 176. 15*s*.

THIS is a valuable book, for the author has been associated with the crystallisation of enzymes from its earliest days, and he has made a full review of the whole field of study. He gives a detailed description of the crystallisation of trypsin, chymo-trypsin, pepsin, pepsinogen and the various peptidases Hitherto most of this material has had to be sought for in the German literature or in the original papers of Northrop himself and various other American writers. It is here set out conveniently and concisely, with a full bibliography and an excellent index.

Diagnosis and Treatment of Diseases of the Thyroid

By JAMES H. MEANS, M.D., Jackson professor of clinical medicine, Harvard University; and EDWARD P. RICHARDSON, M.D., John Homans professor of surgery in the university. London: Humphrey Milford, Oxford University Press. 1939. Pp. 367. 21*s*.

THIS volume of reprints from the Oxford Monographs on Diagnosis and Treatment contains much of value to both physician and surgeon. After a chapter on the historical aspects of our knowledge of the thyroid gland, there are useful summaries of the function and diseases of the gland, and of the principles of diagnosis and treatment. The classification is not always clear. Diffuse non-toxic goitre is discussed under colloid goitre, and diffuse toxic goitre and nodular toxic goitre are treated as two distinct conditions, under exophthalmic and adenomatous goitre, in spite of the statement in the text that true neoplasms or adenomata are not always present in the latter The diagnosis and treatment of these conditions are dealt with systematically, but the rarer complications, such as exophthalmic ophthalmoplegia, postoperative exophthalmos, osteoporosis and so on, receive little attention Myxœdema is considered thoroughly, but the varying grades of hypothyroidism are ignored. Throughout the book there are excellent illustrative case-reports showing the results of treatment, but more definite guides to ultimate prognosis would be welcome. If the reader expects, as he well might from such authorities as these, a discussion on the recent advances in knowledge of the physiology and functional pathology of the thyroid, he will be disappointed. But he will find the book an admirable practical guide to diagnosis and treatment.

Bacterial Metabolism

(*2nd ed.*) By MARJORY STEPHENSON, Sc D., associate of Newnham College, Cambridge; member of the scientific staff of the Medical Research Council. London: Longmans, Green and Co. 1939. Pp. 391. 21*s*.

THIS monograph first published in 1928 has doubled its size, and appears now as "an advanced textbook." The treatment of the subjects is amplified; important additions concern bacterial growth and nutrition, bacterial enzyme systems, nitrogen fixation and the newly opened field of bacterial photosynthesis. The metabolic activities of bacteria are of moment in a great deal of medical, industrial and agricultural bacteriology, but from the vast range of phenomena in these fields the author has selected only those that can profitably be discussed in the light of modern biochemistry. For this reason the textbook will probably be more useful to advanced biochemists than to bacteriologists Facts are for the most part allowed to speak for themselves, and there are few concessions to the uninstructed In scope the book has the stature of a textbook; in presentation it has not advanced sufficiently beyond the monograph written for experts Nevertheless, the medical bacteriologist will find it a mine of digested and documented information, and, what is perhaps more useful, a graveyard of a number of doubtful hypotheses.

Our chief complaint is of the paucity of general comment, which is the more regrettable because Dr. Stephenson is highly illuminating on the rare occasions when she allows herself something more than a rigidly ad-hoc criticism of her material. The book avoids being a series of detached essays on different aspects of bacterial metabolism by a process of historical dove-tailing, but little evidence of any general attitude to the subject is allowed to emerge unless it be a conviction that empiric bacteriology is to be regarded merely as an addition to the complexity of nature. Perhaps the subject is scarcely ripe enough for generalisation. At any rate, until Dr. Stephenson thinks that it is, we must be content with this excellent interim report.

Penn'orth of Chips

Backward Children in the Making. By CHARLES S. SEGAL. London: Victor Gollancz. 1939. Pp 128. 3*s*. 6*d*

DESPITE the title this book is a serious contribution to social science. It gives the results of Mr. Segal's own experiment—the detailed examination of the environment of 26 boys in a backward class. The observation that dullness and poverty are closely associated is strikingly illustrated. Mr. Segal does not, however, confine himself to the task of demonstrating that these two evils are associated; he is at pains to show to what a large extent poverty must be considered the cause of dullness. In doing this the whole body of evidence is taken in review and the opinions of dietitians, psychologists, social workers and others who have devoted time and labour to the subject are freely quoted. The book in fact, though not large, is a compendium of information of interest to doctors as well as laymen. There is a valuable preface by Dr. Cyril Burt.

THE LANCET

LONDON SATURDAY, JULY 1, 1939

FUNDAMENTAL CANCER RESEARCH

ON Tuesday afternoon the new laboratories of the Imperial Cancer Research Fund at Mill Hill were formally opened, within a stone's throw of the new central institute of the Medical Research Council In an address, with which he made the occasion additionally memorable (see p 33), Sir Gowland Hopkins recalls the confusion and pessimism in the medical profession on the subject of cancer which prevailed when the fund was established in 1902 Now the fund has a scientific tradition based on nearly forty years of research by a laboratory staff organised with far-seeing wisdom as a working unit Under the direction of Bashford and Murray this unit has laid stepping-stones in the systematic study of cancer by experimental means Galling as must have been the straitness of its accommodation in Queen Square to the personnel, Dr Gye will recognise the advantage of having waited for a worthier home until the needs of research were well established and the means available to equip an institute capable of supplying them It was certainly time for the fund to do something for its own staff, for there are few laboratories in Great Britain which have not depended for scientific material upon its generosity

The suggestion to found an institute for the investigation of the nature, cause and treatment of cancer originated (as the late Sir Frederic Hallett tells us in the first report of the fund) in 1901 "in some conversation between a private gentleman and a member of the council of the Royal College of Surgeons of England" Sufficient funds were quickly collected to enable investigations to be started, and the new organisation was placed under the joint control of the Royal Colleges of Physicians and Surgeons From the start it was realised that before ever the experimental study of cancer could, with profit and with hope of carrying conviction, be inaugurated it was necessary to gain a conception of the extent and distribution of cancer, and to clear the ground of the dogmas that cancer was a disease limited to civilised man and that it was increasing at an alarming rate Accordingly, with the help of Dr John Tatham of the General Register Office and of the large London hospitals, an examination of the statistics of cancer was undertaken Arrangements were made with the hospitals to check the accuracy of the diagnosis of cancer in a series of 10,000 cases according to the accessibility or inaccessibility of the site of the tumour, and when this was done a striking difference came to light In the accessible sites only 9 per cent had not been recognised clinically, while 7 per cent had been erroneously diagnosed as cancer In the inaccessible sites the percentage of missed diagnoses was as high as 38, while only 9 per cent of cases had been erroneously diagnosed as cancer Similar investigations in the United States and on the Continent have since had similar results Even under conditions most advantageous for diagnosis the number of cancer cases not recognised is surprisingly high for the inaccessible sites, since these are responsible for a large fraction of the whole cancer mortality, the recorded total must be sensibly lower than the actual one When therefore a comparison of the total recorded mortality is made over long periods, we must expect the improvements in methods of diagnosis, and the greater attention paid in recent times to the clinical recognition of cancer, to diminish the number of missed diagnoses and thus increase the recorded mortality If this argument is correct the increase in mortality will be found to fall mainly upon the inaccessible sites—and a glance at the Registrar-General's reports since 1901 proves this to be so Up to the beginning of this century the official figures were not sufficiently detailed to admit of a comparison between accessible and inaccessible sites By arrangement with Dr Tatham provision was made for a more detailed analysis, and in the report for 1903 the cancer cases were classified according to sex, age and parts affected "The arrangement of this column," it was stated in a footnote, "has been fixed after consultation with Dr E F Bashford, director of the Imperial Cancer Research Fund" Thus it was established that cancer is not increasing at an alarming rate in civilised communities and for this contribution to our knowledge we have to thank the fund

During this time the fund, with the generous help of Joseph Chamberlain, was making inquiries about the existence of cancer among the primitive races of the British Empire It was found that almost every kind of cancer known in civilised countries could be duplicated among peoples scarcely touched by what is called civilisation This put an end to another of the dogmas which was inhibiting a rational investigation of cancer A third belief widely held was that cancer is rare in animals, but it is a characteristic of cancer that it is uncommon in the younger age groups, and Bashford found that when animals were allowed to complete their normal span of life cancer was often observed The most satisfactory animal for this purpose is the mouse, being short-lived and kept easily in large numbers It was found possible to establish mouse data, of greater accuracy than human statistics, which showed a cancer incidence rising with increasing age just as in man. Up to 1900 no single cancerous mouse had been found in this country, before the fund had been in existence many years, over 1000 cases of cancer in mice had been observed and diagnosed microscopically With veterinary help the search was extended to all domesticated animals, when cancer was found wherever it was looked for properly. "Cancer," remarked Bashford in his second report, "has been discovered to pervade the whole vertebrate kingdom."

The experimental study of cancer on a broad basis now became possible, it was certain that observations on cancer in animals have relevance to cancer in man. The age-incidence, the mode of origin, the structural characters, the manner of growth and dissemination through the body, and the almost invariably fatal ending were found to be the same throughout the animal kingdom. In no other disease in fact is there such close identity as between cancer in man and cancer in animals. All subsequent experience has verified these early findings of the Imperial Cancer Research Fund. They are now buried in the body of our knowledge of cancer and it is right that they should be recalled at this moment in the fund's history. Since those early days great progress has been made Carcinogenic substances have provided the opportunity to study the inception of cancer; refinements of biochemical technique now enable the chemist to measure the metabolism of the malignant cell; and the discovery of virus tumours by Peyton Rous has given the hope that the discovery of the proximate cause of cancer is not beyond the wit of man. In all these advances the fund has played its part and whatever direction cancer research may take in the future will be profoundly influenced by the work which the fund has already accomplished. The courage and the initiative are there; those who wish the fund well will be content to leave its intellectual freedom completely unfettered.

THE DECLINE IN FERTILITY

THE prospects of a fall in our population, which are causing perhaps too much concern in some quarters and not enough in others, were discussed at length in the House of Lords on June 21. Lord SAMUEL set out the grounds on which the familiar hypothetical estimates have been made and painted a dismal picture of the economic and strategic results that must follow if the estimators prove true prophets. The immediate cause, he said, is no physiological change in the human race but deliberate conscious human action—children are not born because prospective parents do not wish them to be born. The primary cause is largely economic—namely, poverty or the fear of poverty, and consideration of the nutritional, educational and general interests of the children already born. He set no value on treatment of the immediate cause, but, backed by Lord DAWSON, Lord DERWENT and the ARCHBISHOP OF YORK, demanded treatment of the primary disease, by the institution of family allowances. Lord DAWSON put forward, too, the need for parental educational measures to allay the fears of maternity and bring home to mothers and fathers the ultimate wisdom of larger families. Lord SAMUEL and those who came after urged the Government to set up a Royal Commission on fertility, but Lord STAMP, and later Lord TEMPLEMORE for the Government, pointed out that such a commission would have few real data to work on.

The Population (Statistics) Act, which came into force a year ago, will elicit much about human fertility, but many problems outside the scope of figures will remain. Vital statistics, for instance, may tell us what proportion of women who die are childless and how many have had children, but they will tell us nothing of the factors responsible for sterile marriages and little of the influences which induce married couples to restrict their families. A proportion of marriages, we will learn, are sterile. What proportion of these are childless involuntarily or by design? The information obtained by registrars of births, marriages and deaths will throw no light on these intimate questions. In the complex of influences and experiences which deter from parenthood, medical factors play a definite, though as yet unascertained, part. It may be impossible to consummate a marriage owing to various causes affecting both sexes: varying degrees of sterility may be present in either parent, the woman may have had a number of miscarriages or stillbirths; she may suffer from one of many physical abnormalities or chronic illnesses which make pregnancy dangerous or incapacitate her from devoting proper care to her children in their early years, the father's bad health may weaken his earning power or cause misgivings as to his occupational stability, thus taking shape as an economic deterrent from parenthood; lastly, though physically and economically equipped for having children, the couple may hesitate to embark on parenthood because of hereditary defects (real or imaginary) in their ancestries.

The prevalence and importance of such factors as these can only be elucidated by direct inquiry. On another page appears a letter from representatives of the Population Investigation Committee, asking the cooperation of our profession in an inquiry which will bring out facts, on these and other matters, to take the place of the present guesswork. They should meet with a ready response.

WHY FLOGGING SHOULD BE ABOLISHED

PARLIAMENTARY voting on the proposal for the abolition of corporal punishment by order of a court is, we understand, to be treated as a non-party matter, and discussion has been sufficient for current arguments for and against it to be clearly defined. The report of the Departmental Committee on Corporal Punishment provides decisive evidence disproving the assumption that such punishment has any deterrent effect upon the person punished, and some evidence pointing to the likelihood that it has an opposite result. The supposed deterrent effect upon would-be criminals is incapable of such close examination, but oft-quoted positive claims in that direction did not survive statistical inquiry by the committee. It seems, therefore, that there is enough material in the report, when studied as a reasoned statement of cause and effect, to enable our legislators easily to reach a conclusion favourable to the proposal. Yet such a conclusion is by no means certain; as Mr. WILFRED TROTTER said in our columns last week, we cannot separate off the reasoning process as such and set it to work in an emotional vacuum; and opponents of the proposal

frankly appeal to emotion in calling for retribution to satisfy the feeling that those who commit especially horrible crimes should suffer in their own bodies To this emotional appeal there is no easy answer; if we frankly *decide* to let our feelings overwhelm rational judgment how can our claim be resisted?

It is curious that sexual crimes are so often specified as calling for bodily punishment, for a very serious objection to the purposeful infliction of physical pain, by law or otherwise, is the close connexion of such an act with perverse sexual manifestations, a connexion which is rarely enunciated in plain language It is not a matter of unconscious sadism (the existence of which need not come into consideration at the moment) but of conscious sadism which accounts for cases of apparently senseless cruelty and reaches its acme in the lust murders with which our newspapers make us familiar Short of such horrors there exists, among the sex perversions that our civilisation seems to produce, a capacity for receiving a sexual stimulus from the contemplation, in reality or fantasy, of the infliction of pain This capacity is known in early life, often before the nature of the stimulus is recognised by the unfortunate child, and many an adult, who would greet with alarm and admonitions a manifestation of normal sex development in a child, acquiesces in a punitive performance that may actually stimulate a tendency to abnormal sex development When matured, this sadism may in either sex express itself in masturbatory fantasies, or the sexual orgasm may be dependent upon the *actual* or symbolic performance of sadistic acts Medical psychologists find that patients under treatment for various troubles will describe how, perhaps against their will and in spite of their abhorrence, accounts of the wilful infliction of pain will sexually stimulate them, those who, acting voluntarily or under inner compulsion, seek a sexual orgasm by the infliction of severe bodily pain or actual injury on another, are likely to fall, and often do fall, into the hands of the law One hears of the provision of whips in brothels, and the existence of a literature of flagellation appealing to perverts is well known, some of it being disguised and some openly sexual

The incidence of the conditions here briefly described cannot be closely estimated, but those who know enough to recognise them know also that, in varying degrees of intensity, they exist unrecognised all around us Allowing validity to the emotional appeal, we must admit it is horrible to think that any one affected by such tendencies should come in contact with legalised floggings, but there are no means of preventing it The stimulation of the normal sex instinct is ever an object of control and censorship, much worse is the stimulation of one of the most distressing perversions of that instinct, which is inevitable as long as flogging is a part of our legal equipment We must bear in mind those who may be harmfully affected by the discussion or the description of deliberate infliction of physical pain

ANNOTATIONS

WANTED—BLOOD-DONORS

An extensive appeal for volunteer blood donors is to be launched by the Ministry of Health, in coöperation with the Medical Research Council, next week The appeal is for the depots which will serve civilian casualties in London and the Home Counties in time of war, plans for the rest of the country are being made locally A blood supply officer has been appointed to each of the sectors into which this area has been divided, and his duty will be to see that every hospital in his sector, especially those in the central area, could be provided with adequate amounts of blood for transfusion For this purpose a number of stations for enfranchising donors have been set up and will be open daily from 10 to 12 A.M and from 5 to 8 P.M from July 3, on six days a week Volunteers on registration will be grouped, and those who are universal donors will receive a card telling them where to report if an emergency arises Volunteers of other groups will receive cards thanking them for their offer of help and letting them know their blood-groups, in case they should themselves need transfusion Blood will be withdrawn from universal donors immediately war is declared, and stored at temperatures of 2°–4° C until required It is reckoned that 100,000 volunteers will be needed in the London area

Experience in Spain showed that the collection and storage of large quantities of blood for transfusion was carried out most successfully in specially equipped clinics with adequate plant for refrigeration and sterilisation Four such depots, at Maidstone, Luton, Slough and Worcester Park, are now being equipped for the storage of about 1000 bottles each, with the necessary apparatus for collecting and administering blood Blood will be distributed from these centres by refrigerated vans The sites have been chosen because they contain a relatively large population at a reasonable distance from London and are served by a good road system Each depot is expecting to collect a panel of 20,000 volunteer donors, of whom about 8000 will be universal donors About 10,000 donors have already been tested Any healthy person between 18 and 65 is considered suitable to volunteer and for obvious reasons it is hoped to enrol as many women as possible The addresses of centres where preparations have already been made for enrolling volunteers will be announced in the next few days

THE CARDIAZOL FIT

Since desperate diseases call for desperate remedies, psychiatrists were not disposed to reject the new treatment of schizophrenia by insulin and by Cardiazol because these methods, when first seen in action, did not particularly commend themselves as safe and agreeable There were however differences in these respects between the two methods Cardiazol had a certain advantage *Tuto* might be dubious, and *jucunde* definitely not the case, but so much weight could be put on *cito*, as it seemed, that the drug came to be widely employed, even in the wards of general hospitals, and on a variety of psychiatric disorders Dislocations of the jaw, an occasional

fractured femur—these were not taken too tragically, since the great benefits hoped for would outweigh them. Whether this is so cannot yet be decided, but graver complications are now reported On p 17 of this issue Dr. Tooth and Dr. Blackburn publish evidence that the cerebral changes occurring during a cardiazol fit may give rise to impairment of intellectual capacity and memory. This would be a high price to pay especially if the patient depended on his intellect and memory for his livelihood. It is excessively high when one considers that the "spontaneous" remission-rate in schizophrenia is, in any case, not much below that claimed for cardiazol treatment Gelperin,[1] in a recent communication, reports 94 schizophrenic patients who were discharged improved out of a total of 235 admitted to a psychiatric ward, though they had had no other treatment than superficial psychotherapy This would dispose of the argument sometimes put forward that a little hebetude is better than a chronic insanity. Both the chronic insanity and the hebetude can be averted in the case of many schizophrenics if the psychiatrist can afford to be patient and satisfied with the general psychiatric methods that were available before cardiazol and insulin had been introduced Tooth and Blackburn are cautious in their inferences and would not damn the cardiazol method outright because of its occasional untoward results: but the difficulty is to know which cases are the right ones to select for it. The deterioration they report, remarkably confirmed by psychological testing, is not the only complication of cardiazol treatment. The high incidence of vertebral fracture in cardiazol-treated patients has recently been noted in America.

PRIVATE WARDS FOR CHILDREN

It is said that when a certain royal personage was ill his surgeon assured him that he would be looked after as well as if he was a hospital patient, and he was comforted. Some such thoughts must have been in the minds of the management committee and medical staff of the Hospital for Sick Children, Great Ormond Street, in their rebuilding, for in providing private wards on the seventh floor they seem to have set out to give the child whose parents can afford to pay for it as happy and as profitable (in the health sense) a time in hospital as his poorer brothers and sisters in the floors below. There are single-cot rooms, which can be curtained off for privacy or opened into one another to provide for a nanny or other social amenities, for twenty children, and two small wards of four cots each provide that type of companionship in disease which is so often of great disciplinary value in treating minor behaviour problems Each room opens on a large balcony, well protected by railings and wire netting, with an unrestricted south aspect to let in sun and air. While forming an integral part of the whole hospital and thus sharing in all the modern services available—with oxygen on tap, mobile electric lamps and other accessories—the private floor has its own entrance, waiting-room, consulting-rooms and operating-theatre Rooms are set aside for nursing mothers, and "at the absolute discretion of the medical staff" single rooms, if available, may be used for mothers and nannies. It is probable that in this phrase quoted from the regulations lies the greatest advantage of the hospital over the home in the treatment of the sick child. Handed over to the care of skilled nurses accustomed to humouring and amusing the sick child on a basis far removed from that of the home nursery, the small patient makes quick adjustments which are only slowly reached, if ever, in the atmosphere of a home upset by the advent of illness. For surgical procedures such a programme has obvious advantages, and for the many medical disorders in which a psychological process is playing a dominant or even subservient part the complete change in environment, human as well as physical, produces results which have long been recognised among the ordinary hospital patients Great Ormond Street is not the first children's hospital to open accommodation for private patients, but thanks to the generosity of Lord Nuffield it has been possible to incorporate in the rebuilding scheme a unit which should serve as a model of its kind.

A COLLEGE FELLOWSHIP IN CLINICAL SCIENCE

With the inauguration of a department of medicine the opportunities at Cambridge for clinical and correlative research work are now greatly improved But whereas numerous college fellowships in the past have been available for graduate students of physiology and pathology there has hitherto been no recognition of clinical science as an appropriate subject for a fellowship, partly because facilities were lacking and partly because clinical science was not yet accepted as worthy of inclusion among the other natural sciences. This acceptance is now becoming general, and the announcement that a Stringer fellowship at King's College may on this occasion be awarded to a candidate whose study or research falls within the group of subjects including clinical medicine marks a further stage in the development of scientific medicine at Cambridge For a man of suitable qualities the prospects and amenities of the appointment should offer strong inducements. Candidates must be members of the university, under thirty years of age on Dec 6, 1939 Any candidate who is in doubt if his study or research falls within the prescribed group should consult the Provost, to whom applications should be sent by Oct 16

ASEPTIC NECROSIS OF BONE

When the pressure in a diving-bell is reduced too suddenly gas is liberated from the tissues more quickly than it can be removed by the blood, and the symptoms of caisson sickness may result. In discussing the aseptic necrosis of bone that sometimes follows, and quoting four cases with autopsy or biopsy findings, Kahlstrom, Burton and Phemister[1] point out that when the body is exposed to high atmospheric pressure the gases of the air are absorbed in different degree according to the nature of the tissues Thus fat or lipoid tissue such as the nervous system absorbs about five times the amount of nitrogen that water or serum will take up, and it is such tissues that are likely to be most damaged by the liberation of gases during decompression. Oxygen is relatively easily dissolved and got rid of, but the bubbles of nitrogen set free in the fatty marrow of long bones give rise to emboli which may obstruct end-arteries and produce necrosis. If this necrosis affects the bone bordering a joint the weight-bearing portions of the bones may collapse and there may be lesions of joints, sometimes with the formation of intra-articular foreign bodies This process lends support to the view that arthritis deformans, in which the lesions are much the same, may be due to

1 Kahlstrom, S C, Burton, C C, and Phemister, D B, *Surg Gynec Obstet* Feb 1, 1939, p 129

vascular blockage and necrosis of the bone underlying articular cartilage

In a second paper [2] these American authors describe massive multiple infarcts of bones arising without exposure to compressed air The pathological and radiological appearances in some cases closely resembled those following caisson sickness The etiology of these infarcts is obscure, but the authors suggest that they may be related to the idiopathic lesions sometimes seen in late childhood It also seems possible that there is a relation between these presumably embolic conditions and "Paget's quiet necrosis," which is discussed by Hundenach in this issue Quiet necrosis may it seems, be due to trauma with a superimposed low grade staphylococcal infection, but its results are not unlike those due to infarction

ARTHRITIS IN ANIMALS

THE professor of comparative pathology at the University of Pennsylvania has lately described [3] the lesions found in 777 specimens out of 1749 dried skeletons in a number of museums, as well as similar lesions in wet cleaned bones examined during three years in the pathological service of the Zoological Gardens in Philadelphia Even in wild animals he finds signs of arthritis corresponding to those seen in man These, however, are confined to the larger animals, including apes, hyenas, bears, oxen, stags, and the cat tribe, and none have been observed in the dog tribe or in rodents or bats Domestic animals are not included in this study, but it is known that draught horses, for example often show arthritic changes in the joints

Some skeletons of gorillas present lesions which correspond, in Prof Fox's opinion, with "all varieties of arthritis" found in man In the wild boar the larger bones show ridging, as if muscular insertions had pulled upon the periosteum and produced overgrowth This is interpreted as a 'senile periosteal overgrowth, possibly a tension or traumatic reaction" Four bears in the zoo were "not suspected of having such severe articular disease," and the same may be said of the joints impaired simply by overwork in some elderly men and women An old grizzly had general hypertrophic arthritis, the anterior extremities being especially affected, with more advanced changes in the right metacarpals than in the left Among the hyenas 9 out of 16 specimens had widespread lesions—"a very striking picture" In these animals there is great development of the anterior musculature and the lesions in the hind limbs were negligible It should be noted that arthritis is not found in young menagerie animals with which may be contrasted the high incidence of rheumatoid disease in early adult age in man

Prof. Fox cites many facts which suggest a correlation between function and lesion, such as the hand and foot lesions common in primates and the liability to arthritis in the muscle joint combinations that bear the greatest strains joits or shocks His radiograms and descriptions of animal lesions are typical of osteo arthritis, a wear-and tear disease of adult or later age, in which strain and traumatism and degenerative processes—often premature—play the chief part It is widespread in the world and was perhaps as prevalent in early times as it is today That it occurs in the larger animals, subject to the same causal influences, is a significant fact On the other hand there is, we believe, little or no evidence that animals are affected by rheumatoid arthritis, now usually regarded as an infective and atrophic disease in which neither degenerative changes nor the influence of trauma can be traced

BLOOD-LETTING FROM THE FEMORAL ARTERY

IN obese patients with falling blood pressure and collapsed veins, blood letting may sometimes be desirable but difficult Greatly daring, as some may think, Emile Weil [1] has devised an alternative method which he has found both simple and satisfactory In cases where venesection is troublesome or impossible, he inserts a trocar, directing the point upwards, into the femoral artery, which even in the most collapsed patients is always easily identifiable by its pulsation By this means it is possible, he claims, to withdraw any desired quantity of blood quickly and without risk of clotting or subsequent hæmorrhage For the sake of convenience and tidiness he recommends that the blood be caught in a flat graduated basin When enough blood has been let, the trocar is withdrawn and pressure is applied to the puncture for half a minute This, aided by the elastic recoil of the arterial wall, seals the wound completely Emile Weil cannot see why the method should fail even in the most inexpert hands It will perhaps commend itself to the courageous, though they may like at first to include a tourniquet in their arteriosection kit

LIVERPOOL HOSPITAL SCHEME

As a preliminary step in launching a public appeal for funds to build a new voluntary hospital in Liverpool, Mr A V J Hinds, in a booklet entitled "Hospital Testament" (University Press of Liverpool, Hodder and Stoughton Ltd, 6d) asks why so necessary a thing as hospital treatment should depend on charity. Why not a state hospital service? Granted the necessity of state hospitals, how can the continuance of voluntary hospitals be justified—much less a progressive or intensified activity? In Liverpool, he says, the voluntary hospitals are saving the municipal authorities an annual expenditure of over £150,000 In Great Britain there are 1000 voluntary hospitals with a combined income of over £17,000,000, over 40 per cent of which comes from voluntary sources and relieves the community of an annual expenditure of over £7,000,000 The care of the sick is only one part of what a hospital service does for the community The hospital is really the source of all private medical service—general practitioner, consultant and specialist Research in clinical medicine is non productive without the hospital because in a hospital alone can be collected a sufficiency of cases The service provided by the hospital is thus threefold curative, educational, and scientific The lay committee of a voluntary hospital, it is argued, is independent, not swayed by political or bureaucratic motives, and is a guarantee that the best available persons will be selected for staff appointments, the selection actually being made for merit alone by professional colleagues and not decided solely by a political body or a lay administrator This means that the "best brains" serve not only as healers of the sick in hospital but also as university teachers and leaders of research In

3 Chronic Arthritis in Wild Mammals. By Herbert Fox professor of comparative pathology University of Pennsylvania Philadelphia The American Philosophical Society 1939 Pp 76 9s

1 Emile Weil P., *Bull Soc méd Hôp Paris* May 29, 1939 p 802

other words, the voluntary hospitals guarantee an alert and enterprising medical profession

In Liverpool the nine voluntary hospitals associated with the medical school of the university have about 1400 beds, whereas the municipal hospitals have about 3000. It is recognised that the municipal hospitals have come to stay, and the policy of the voluntary hospitals in Liverpool does not envisage any increase in the number of existing beds in the voluntary hospitals in that area The voluntary hospitals serve a large area extending to north Wales and south-west Lancashire, whereas the municipal hospitals can deal only with patients from within the city boundaries For over three years there has been in existence in Liverpool an Associated Voluntary Hospitals Board, which has attempted to unify the policy of the voluntary hospitals, and it works with the Municipal Hospitals Committee on the Liverpool Hospitals Joint Advisory Committee. The four general hospitals (the Royal, the Northern, the Southern, and the Stanley) were amalgamated in 1938 to form the Royal Liverpool United Hospital. They will have to be almost entirely rebuilt within the next twenty years; so it has been decided to substitute for them, close to the university, one general hospital with 850 beds, the total now spread among the four; to coördinate so far as possible the activities of the special hospitals in the system; and, when the time comes for rebuilding each special hospital, to try to relate it to the new hospital in some sort of hospital centre The four existing sites would be adapted as outpatient and casualty departments to serve the different areas.

RADIOSENSITIVITY OF MELANOMA

RADIOSENSITIVITY is a term that is often misunderstood To say that a malignant tumour is radiosensitive implies only that it shrinks under the influence of radium or X rays; this is a purely macroscopic phenomenon, and is by no means always accompanied by the disappearance of all viable malignant cells This use of the word gives rise to the paradox that many of the most radiosensitive tumours recur at the primary site and kill the patient, for radiosensitivity and a high degree of malignancy often coexist On the other hand, radioresistant tumours, though they are often among the least malignant, also kill their host because they do not respond to treatment It is therefore clear that sensitivity and resistance need not be related to the final result and prognosis There is a widespread belief that because melanomata are rarely if ever cured by radium or X rays they are therefore quite insensitive, but Ellis[1] has now shown that this is often not so, for he describes 12 cases in which the tumour regressed after irradiation This is not to say (and Ellis does not say it) that this form of treatment is as promising in melanomata as in other tumours Ellis records a series of 38 cases seen at the Sheffield radium centre in the years 1931–37 Excluding untreated cases and those in which an eye with a primary growth was removed, there remain 27 cases in which it is possible to attempt to assess the value of radium or X rays Of these, 8 have lived for periods ranging from one to six years without recurrence It is of course possible that in some of the others life was prolonged and recurrence delayed by the treatment; improvement as distinct from cure is difficult to estimate The fact remains that less than 1 patient in 3 can have been cured. Thus, though it must now be accepted that some melanomata are certainly radiosensitive, it has yet to be proved that in these tumours irradiation is the treatment of choice

FREDERICK HOBDAY

ON the evening of Oct. 24, 1923, Clifford Allbutt presided at a memorable occasion, of which the object was to celebrate the unity of medicine as a biological study It was the first meeting at the Royal Society of Medicine of the section of comparative medicine As physic was divorced from surgery and mind from body, so, said Allbutt, had medieval perversity separated diseases of animals from those of mankind

[Harrods

We recall this occasion because it was the aim of Hobday's later life to bring the animal medicine in which he had been bred and born into fruitful relation with human medicine. He was the first veterinary president of the new section And it was not merely the utilitarian side of the relation which interested him He was particularly conversant with the diseases common to man and animals; his own work lay largely in that direction, and he had been highly successful in applying Listerian methods to veterinary surgery. But he was convinced of the place of veterinary science in the larger medicine, if only because the material of study, ranging over *many general and even orders of the animal kingdom*, was more broadly based than that of medicine, which observes a single species It was this conviction which led him to devote the fund raised on his retirement to the inauguration of a chair of comparative medicine and of a doctorate open equally to graduates of the human and the veterinary branches of medicine. He had been invited by the Chadwick trustees to deliver a lecture on this theme which was to have been the crowning achievement of his life. All those who knew him as friend of man and animals might unite to ensure that his purpose is still achieved.

On his own ground too Sir Frederick Hobday deserved his popularity and success Having qualified in 1892 at the Royal Veterinary College he began at once to teach there and soon made up his mind that veterinary medicine was not going to flourish in effete surroundings What was good enough for St Bel in 1790 was not good enough in 1900 for the chief centre in this country of veterinary teaching. Hobday soon showed that he could get things done, and, equally to the point, that he could persuade people to provide the necessary funds for doing them He raised nearly £300,000 for the new buildings in Camden Town and remained principal until they were opened by Royalty. During the whole time he was principal of the college he was also president of the organisation devoted to animal welfare now known as U F A W, which appealed to him as the embodiment of practical humaneness He was indignant of cruelties to animals under whatever guise and helped to espouse measures to eliminate

needless suffering From his earliest days he worked on the problem of anæsthetising animals and birds and it was his apparatus which first made it possible to administer chloroform safely to dogs The elaborate chapter on the administration of anæsthetics in the recent fourth edition of his "Surgical Diseases of the Dog and Cat" is largely a record of his own effort It has been said with some justice that Hobday thought not so much with his head as with his heart, but animal life may feel content with that kind of thinking

A SIMPLE WAY OF KEEPING MILK

FRESH milk is a temperamental and unstable fluid, inclined to rapid and devastating loss of flavour, and many ways have been tried to prolong its life beyond the few hours which any but the cleanest milk will keep under average temperature conditions Pasteurisation, sterilisation, 'buddensation' and the Hoflus process are all used or have been used, but most of these methods require complicated and expensive apparatus Now Davis[1] of the National Institute for Research in Dairying has described a surprisingly simple method that may prove of great value in conserving milk for days without the use of elaborate machinery It consists in adjusting the pH of the fresh milk to 6·2 with dilute hydrochloric acid and maintaining it at between 36° and 38° F In this way the milk may be kept for a fortnight or more—that is, three or four times as long as commercial cooled pasteurised milk will keep—and may then be brought back to its original pH before use by the addition of an equivalent amount of dilute caustic soda The result is a milk that is said to retain its original flavour unchanged So far the method seems to have been tried on only a small scale, but if it proves equally effective on a large scale it will have several obvious applications in the milk industry It will remove one of the minor annoyances of ocean voyages of up to a fortnight's duration, it will simplify the adjustment of supply to demand over the week-end, and it will help the manufacturer of milk products to deal with a rush period when for a few days the inflow of milk may exceed the capacity of his machinery In time of war, when delays in transport may be both unpredictable and unavoidable, it might be a convenient way of treating bulk milk carried in tanks by road or rail. Further information is needed as to the viability of the commoner pathogenic organisms in milk acidified in this way, and as to the possibilities of combining the method with pasteurisation Various difficulties besides the mechanical one of adding acid and alkali to milk on a large scale may have to be overcome before commercial success is attained, and unfortunately legal considerations may also weigh heavily against the process, for it involves diluting the milk to the extent of some 8 per cent

LOCAL EFFECTS OF ADRENALINE

THE inhalation of a vaporised solution of adrenaline as a treatment of bronchial asthma was introduced some four years ago and is now used extensively The strength of the solution has been progressively increased from the original 1 per cent, and a 10 per cent solution is now often prescribed Galgiani and his colleagues[2] have lately investigated the local effects of these solutions on the pharyngeal and bronchial mucous membranes By trieing the course of gentian violet vaporised in the mouth of a patient with a bronchial fistula they showed that most of the inhaled vapour is deposited on the pharynx, larynx and trachea, a finding that agrees with the conclusions of Spoto[3] and Rubow[4] that in dogs and rabbits not more than 3 per cent of the inhaled vapour reaches the lung They next showed that clinically the adrenaline deposited on the mucous membrane of the upper respiratory tract usually has no systemic effect, and they confirmed this fact in cats, but they found that the bronchial mucosa of cats absorbs adrenaline well, pulse and blood pressure changes being demonstrable after the deposition in a bronchus of 0·0002 mg To reach an equivalent concentration in the human bronchus by inhalation would, however, require something like a hundred inhalations They concluded that the anti asthmatic effect of the drug is due to its direct action on congested bronchial mucosa and spastic musculature, and not to its absorption into the general circulation

The next part of their work dealt with the effects of long continued use They were able to show that repeated inhalations produce pharyngitis and tracheitis in animals, and that swallowing the solution causes gastro intestinal changes A man who died of pulmonary tuberculosis after having frequent inhalations of 1 per cent adrenaline during the 48 hours before death also showed post mortem signs of pharyngeal and tracheal irritation Some time ago Fox[5] demonstrated the destructive effect on the respiratory mucous membrane of the prolonged application of adrenaline and ephedrine, and most laryngologists are familiar with the patient complaining of "nasal catarrh" who has used one of the proprietary preparations containing adrenaline, ephedrine or Benzedrine for a long time, and with the cure that results when it is discontinued The conclusion is unavoidable that adrenaline and similar compounds are unsuitable as local applications to the upper respiratory tract except for brief periods, and that their repeated use in chronic disease is therapeutically unsound

EXCRETION OF CALCIUM AND MAGNESIUM

THE impression is still widely held that the excretion of calcium and the heavy metals takes place largely through the gastro intestinal tract There is already doubt, however, as to the excretory function of the bowel in the case of iron, in fact the body seems to have little ability to excrete iron at all when once it has been absorbed, and lately doubt has also been thrown on the part played by the bowel in the excretion of calcium and magnesium The calcium of the fæces can theoretically be regarded as made up of three fractions (*a*) the unabsorbed calcium of the food, (*b*) the calcium secreted into the bowel in the digestive juices and not subsequently reabsorbed, and (*c*) the calcium excreted specifically direct into the bowel. McCance and Widdowson[6] have studied the excretion of calcium and magnesium in the form of gluconates after intravenous injection in normal people, and have found no evidence of specific excretion of the injected metal into the bowel the injected calcium or magnesium was indeed excreted rapidly and nearly quantitatively, but the additional excretion took place almost entirely by way of the kidneys and there was no increase in the calcium or magnesium

content of the fæces The ratio of fæcal calcium or magnesium to the intake in the food was unchanged by intravenous injection of large quantities of the metal It seems, therefore, that the intestine has little or no regulatory action in connexion with the excretion of calcium or magnesium, which is in agreement with the earlier results of Nicolaysen,[7] and that the calcium or magnesium of the fæces consists merely of that unabsorbed from the food together with that secreted in the digestive juices and not reabsorbed. This conception is easier to reconcile with clinical findings than the older view of a specific excretory function of the bowel, for the majority of diseases which lead to decalcification, such as hyperparathyroidism and hyperthyroidism, do so chiefly by increasing the urinary excretion of calcium, the fæcal calcium being usually little different from normal Experimental procedures, such as the administration of parathormone or acidifying salts, also increase the urinary calcium without having any significant effect on the fæcal excretion. The only conditions in which the fæcal calcium is appreciably raised are those such as steatorrhœa, where the effect is much more likely to be due to interference with absorption than to normal absorption and excessive intestinal re-excretion.

Surgeon Captain J A. MAXWELL, O.B E , F R C S E, who accompanied the King and Queen on their voyage to America and back, has been created a commander of the Royal Victorian Order.

The British Hospitals Association has appointed a war emergency committee to consider what part the voluntary hospitals should play in the scheme of hospital services in the event of war. The proposal arises from the belief that adaptation and organisation are essential if the voluntary hospitals are efficiently to perform the service which would be expected of them in a national emergency. The committee consists for the most part of lay officers of hospitals in London and thirteen other large towns, but in three cases a medical man has been nominated by the hospital: Mr. Harold Collinson (Leeds), Prof. T. B. Johnston (Guy's), and Mr. C Max Page (St Thomas's). Mr. O. N. Chadwyck-Healey is chairman of the committee and its secretary is Mr. A. G. L. Ives (address 12, Grosvenor Crescent, S.W.1.).

FIRST-AID AT ST. MARYLEBONE

THE borough of St. Marylebone staged a demonstration of the work of stretcher parties and a mobile first-aid post on June 21. Some houses undergoing demolition were used, and the onlookers and the mobile first-aid post were placed in an adjacent plot of waste ground It was assumed that the houses had been damaged by a high-explosive bomb, the warning had been given, and the rescue-parties had released the people under the wreckage. The exercise began with the arrival of the stretcher-party combine, consisting of the stretcher party in its car, an ambulance, and a car to carry sitting casualties. Along with the combine came the mobile first-aid post in a lorry. Immediately on arrival the stretcher-party combine started work, and it became apparent why the various units must be considered as a combine and not as having little connexion with each other. In this case the work of the stretcher party and the ambulance crew dovetailed without a hitch, but it was easy to see the kind of confusion that would arise if cooperation was not carefully prepared

While the stretcher-party men were administering simple first-aid and bringing out the casualties, the mobile first-aid post was being unloaded from its lorry and set up for work in the open Standard equipment was carried, and a staff of one doctor, six nurses, and two male attendants Ministry of Health regulations do not allow any male attendants for a mobile first-aid post, but the exercise demonstrated clearly that they are needed. Casualties were then helped or carried from the houses and disposed of: the gravely injured by ambulance to the nearest hospital, and those whose injuries were such they they could wait for full surgical attention to the first-aid post The trivially injured also were taken to the post, and it was explained that some of these could be discharged without further attention at the hospital.

It was seen that the mobile first-aid post acted as a screen for the hospital and prevented it from being crowded with the full number of casualties, although the importance of this could not fully be demonstrated on such a small scale, with only about a dozen casualties In reality, as is taught at the Home Office A.R P. staff school, it is unlikely that raids would consist of widely scattered bombs; bombs would fall in groups or "patterns," the full load of a squadron of aeroplanes (about 9 tons) being dropped in one small area

This concentration of the attack would have many important effects. The number of casualties in the damaged area would be large, figures for the late war and for the Spanish war point to something like 75–100 casualties per ton of high explosive It was noticeable that the mobile post was only able to deal with two or three stretcher cases and five or six walking cases in about three-quarters of an hour, despite the fact that the work was mere demonstration and not actual surgery In war very large numbers would have to be dealt with, and moreover, if Spanish figures are to be trusted, only 15 per cent of these would be walking cases Before he could start work, therefore, the doctor would have to spend a good deal of time inspecting the casualties and deciding which should be attended to first. If the mobile post were working in close contact with the stretcher party in the damaged area, there is little doubt that he would also be called on to decide which casualties should go direct to the hospital and which should be attended to at the post This would mean that there would be a considerable delay before he could start any actual surgery. It therefore seems that there should be another doctor on the spot to classify casualties, or all casualties should be taken as quickly as possible to a post arranged to deal with the full number[1]

Here the post was set up in the open and not in some convenient building This presumably was done for demonstration purposes, so that the work could more easily be seen Yet in actual war conditions the strictly limited protection of an ordinary building would be little comfort to casualties who had so recently experienced the effect of high-explosive bombs on similar structures It is to be hoped that the recommendation of the Hailey report that such work should be done in full shelter is soon to be carried into effect.

IMPERIAL CANCER RESEARCH FUND

OPENING OF NEW LABORATORIES

On June 27 Sir Humphry Rolleston deputised for Viscount Halifax, the president of the Imperial Cancer Research Fund, in formally opening the Fund's new laboratories at Burton Hole Lane, Mill Hill. The laboratories were moved to Mill Hill from Queen Square a year ago and have been in use since last July. The choice of site was determined by the decision of the Medical Research Council to build their Central Institute at Mill Hill, for it was felt that the small and highly specialised staff of the fund would benefit by direct contact with colleagues with interests in other fields. The new buildings provide facilities that are far in advance of any that the fund's staff have enjoyed hitherto.

SIR GOWLAND HOPKINS'S ADDRESS

At the opening ceremony Sir Gowland Hopkins spoke on the importance of laboratory effort in cancer research. "I have spent much of my life in laboratories," he said, "and it has been one of my main interests to try to follow the effect of that great increase in the number of laboratory workers which has occurred in my time, not only in this country's contribution to scientific knowledge as a whole, but to medical progress in particular." He recalled the time when accommodation and opportunities for experimental research were sadly to seek in this country. It was then the almost universal custom among young men who hoped to devote some of their energy to scientific research to spend an apprentice year or two abroad, usually in a German laboratory, where inspiration and adequate equipment might in those days be most easily found. For this expatriation, he said, there is happily no need today, but the provision of still more laboratory accommodation would benefit both science and the country. Increases in the accommodation provided for skilled laboratory effort have never failed to be justified by results. In growing science the Law of Diminishing Returns finds no application. Our knowledge of nature has grown great, but the extent of our ignorance is much greater.

THE EXPERIMENTAL METHOD

In emphasising the extreme importance of laboratory activities in the world-wide endeavour to solve the problems of cancer, Sir Gowland Hopkins hoped that he would not be thought to be undervaluing the knowledge won by other means or the skill with which existing knowledge is applied by those whose immediate task is to relieve suffering. Of the more recondite aspects of the cancer problem the lay public usually know but little, and there are many who fail to recognise the importance of their study. Yet it is most unlikely that a complete mastery of cancer will arrive until we reach to fuller knowledge of its intimate nature as a phenomenon of uncontrolled growth. But knowledge of this kind must be sought deeper down in the nature of things than can be reached by observation alone, or by any superficial method of study. While the cure of cancer must become ultimately a medical problem, to discover its fundamental nature is a biological problem of great complexity. We are at least not likely to reach any solution of this without sustained efforts based on experimental methods. These in particular are the task of the laboratory.

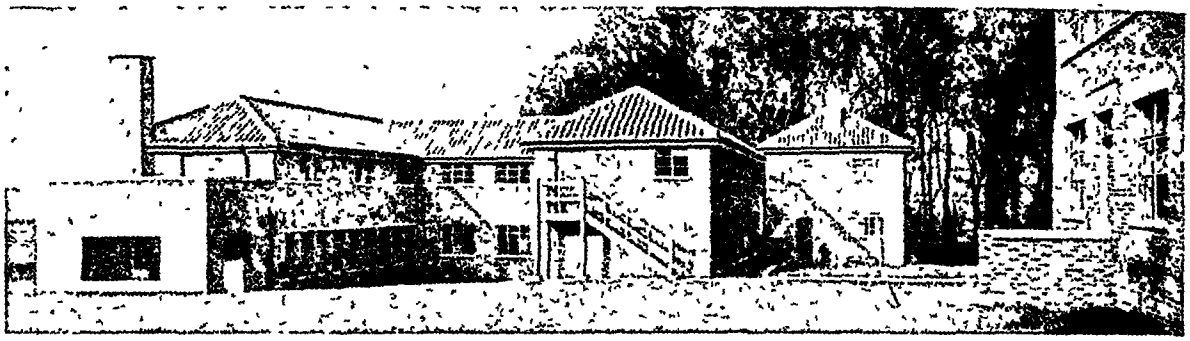
Of the many possible illustrations of the special advantages of the method of experiment Sir Gowland Hopkins chose the establishment of the distinction between typhus and typhoid fever. William Jenner compared side by side every characteristic of the two diseases which could be observed and recorded and this in a great number of cases. In sum, the evidence as one reads it today seems not far from being conclusive. But each individual item contained in the evidence lacked constancy, each contributory argument could be criticised, and was criticised, by many. Complete conviction did not come. Meanwhile, Pasteur the experimentalist was at work. Only a few years had to elapse before his brilliant and carefully controlled experiments had established, once for all, the microbic origin of infective diseases. It was still some years before the exact nature of the specific agents responsible for typhoid and typhus fever could be described, but this was merely a question of developing technique. Such evidence was bound to come after Pasteur had once started the right lines for thought and method. Real progress, and even important generalisations may doubtless result from the recording of systematic observations on aspects of phenomena directly revealed to the senses and in the established conditions of ordinary experience. In cancer research morphological studies have yielded indispensable information but they could throw little light on the underlying phenomenon of morbid growth. It is characteristic of the experimental approach to phenomena that it often yields knowledge of a kind quite unforeseen. The unknown aspects of nature that it reveals are of course part of reality, and only remain unknown because in our customary contacts with nature the conditions which reveal them to our senses are not established. The experimentalist chooses his own conditions.

Many people are inclined to say "we know that the experimental method has created subjects like modern chemistry and physics, but do not the problems of cancer belong to a category quite different from that which included subjects such as these?" We are sure today however that, like so many other biological problems, those of cancer are closely interwoven with those of the fundamental sciences.

Some years ago it used to be said that we shall never fully understand the manifestations of cancer until we have solved the riddle of life itself, with the implication that this will always remain unsolved. Such a view needs much qualification. At one level at least of their organisation living tissues are essentially physical and chemical systems, and it is at this level we must expect to find a basis for the differences displayed by cancer cells and normal cells. If the material basis of life has exoteric qualities which are neither physical nor chemical, these will not intrude into this particular arena.

EARLY WORK ON CANCER

The Imperial Cancer Research Fund was founded, Sir Gowland Hopkins went on, at a time when extreme confusion and pessimism prevailed in the medical profession on the subject of cancer. It was held for instance, by most to be a constitutional disease due to obscure qualities in the make-up of individuals which involved a liability to the disease from which

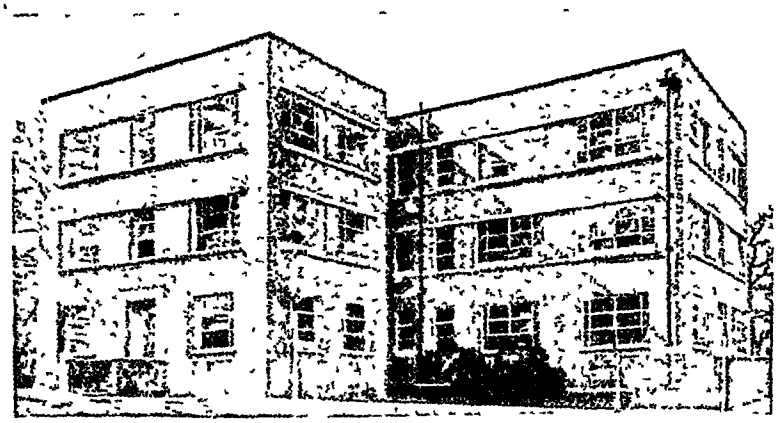


The animal house. The building accommodates rabbits, guineapigs, chickens, fish and dogs, and contains two small laboratories. Larger animals such as sheep, pigs and goats live in houses in the meadow to the north-west of this building.

there could be no escape Yet not a few believed it to be an infective and even a contagious disease inherent in civilisation itself The highly civilised communities, owing to luxury and artificial habits in matters of food, drink and the like, were supposed to have acquired a liability not suffered by primitive races or by wild animals which live more in accord with the demands of nature. These and other dogmas current a generation ago, while inconsistent among themselves, were all of a kind to make the situation seem hopeless in respect both of the prevention and cure of the malady. The belief moreover that animals do not suffer from it was for would-be students of cancer most discouraging, because in the case of maladies suffered by both man and animals so much had been learnt for the benefit of the former by studies carried out on the latter.

The earlier years of this century saw the beginning of devoted efforts which have now replaced inhibitory dogmas by illuminating facts, and the outlook has changed and greatly brightened The belief that cancer arises only in civilised communities was fated to disappear entirely as soon as more extended inquiries had proved its frequent occurrence in primitive races That animals are liable to cancer had, as a matter of fact, been demonstrated before the end of the last century, and further confirmed early in this. The highly significant fact had also been established that if a few cells from a tumour arising spontaneously in an animal were transferred to the body of another of the same species they will there continue to grow and divide, thus producing a tumour in their new host in all respects similar to that from which they were derived. The significance of these facts was at first not generally grasped and the evidence was received with apathy and disbelief Yet the modern and really progressive phase of cancer research began with a recognition of their significance, and the earliest work supported by the Imperial Fund greatly helped to initiate this progressive phase. The foundation of the fund in 1902 was indeed most timely; and, fortunately, its original staff was fully alert to the extreme importance of tumours shown to be transmissible, as illustrating one aspect at least of the essential nature of cancer. Its first director of research, Dr E F Bashford, recognised clearly that so long as the study of its incidence was restricted to its incidence in civilised man progress must at best be very slow, and, in fundamentals, perhaps impossible Investigations therefore had to be placed on a broad basis of comparative, statistical, and experimental studies

Dr Bashford contributed much to the proper interpretation of the available statistical data, and the fund has maintained its interest in this side of research; it possesses today a very expert statistical subcommittee The main activities of the fund's laboratories in the first years were devoted to a thorough and enlightened study of transmissible cancers. With increasing experience spontaneous tumours of various types were found to be by no means uncommon in animals, and they occurred in a variety of vertebrate species. When a few cells from any one of these growths were transferred to another animal of the same species their growth continued, forming in the new host, as the much more limited earlier experiments had suggested, a tumour identical with that from which the cells originated. It was also established that the implanted cells did not induce malignant growth in the normal cells surrounding them The tumour was formed from their own progeny alone. These facts illustrate a fundamental aspect of the nature of cancer, and their establishment at once gave a more hopeful outlook



The main laboratories In ground plan the institute is shaped like the letter T. The wing to the left is used exclusively for animals under experiment. The library, office, workshops, staff tea-room and store-rooms are on the ground floor, while the laboratories, operating-theatre, &c, are on the first and second floors

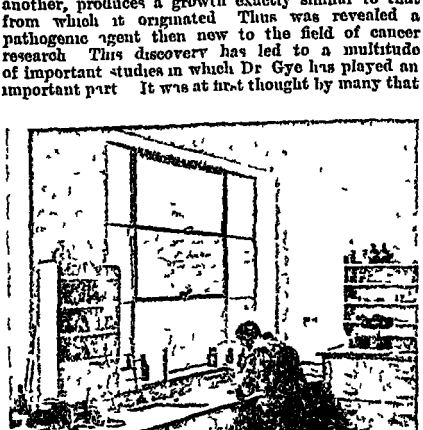
for the surgeon's art Cancer was shown to have local origins, and not to be a constitutional disease That is why the removal of a growth at a sufficiently early age may completely eradicate the disease

The conviction grew that malignant cells possess everywhere the same fundamental properties, and this is the foundation on which the experimental investigations of cancer, as it exists today, is built Of the diseases which can be produced experimentally few, if any, simulate the human disease so closely as cancer The laboratory of the fund, directed after Dr Bashford's death by Dr J A Murray, did more than any other centre at that time to establish these important aspects of knowledge The fund's staff were pioneers in this country in the systematic study of cancer by experimental means Since they began their labours centres for cancer research have greatly increased in numbers, and are to be found in nearly every civilised country It was twenty years after the foundation of the fund that the British Empire Cancer Campaign began to administer the large endowment for research which its appeals to a generous public have provided There is abundant room today for the widespread activities of the Campaign and for the independent efforts of the Imperial Fund

The library

TREND OF RESEARCH TODAY

In 1911 Dr Peyton Rous of the Rockefeller Institute in New York described a form of cancer in the domestic fowl which could be propagated not only by grafts of its cells but by cell free filtrates made from them A small quantity of such a filtrate from a tumour present in one bird when injected into another, produces a growth exactly similar to that from which it originated Thus was revealed a pathogenic agent then new to the field of cancer research This discovery has led to a multitude of important studies in which Dr Gye has played an important part It was at first thought by many that the growths yielding these active filtrates were not true cancers, but the supposed distinction has since lost its significance Cumulative evidence has brought conviction that the pathogenic agent in such filtrates is a virus It belongs therefore to a class of agents now well known as being the effective cause of various diseases in man, animals and plants Characteristic of viruses is their ability to multiply in the body of the infected host, but unlike bacteria they do so only as tenants of living cells



A corner of one of the research laboratories Large windows like this one are provided throughout The benches are supported by the cantilever system.

In a great number of cases at least, he said, we have to recognise in the file of cancer causation the initial influence of an external agent which, acting from the environment, may cause normal tissue cells to become cancerous Such may perhaps be called provocative factors in the field of causation When one of them has acted for a sufficient time, which fortunately is usually a very long time, tissue cells previously exercising only their proper physiological functions may be led to grow pathologically The influence of many of these external factors has long been recognised Long contact with certain chemical substances is one of them, as in the so called occupational cancers Workmen liable to continued contact with shale oil products, with tar or soot, and more rarely with arsenic, aniline and some other substances are prone to develop cancer Long continued mechanical irritation may induce it and also long exposure to certain forms of radiation, as was shown by the sufferings of those who worked with X rays and radium before their power to produce cancer was known

Such causative influences are exerted most readily on the skin and superficial parts of the body, and their effects are there easy to observe It is quite possible however that provocative factors, doubtless differing in kind from these, are concerned in initiating growths elsewhere in the body Such effects are apt to be spoken of as being due to prolonged "irritation," but irritation is a word with vague meanings, and we have to learn why only in certain circumstances does irritation become a stimulant to growth To attain a more definite understanding of the phenomena involved we must study the nature of internal events in tissue cells which pass from quiescence to active growth It is necessary, for instance, to discover whether the growth provoked by an external agent is always associated with chemical or physical changes in the internal economy of the cells and, if so, to learn what is their precise nature If constitutional changes must exist before growth can begin, we should look on their establishment as involving

links in a chain of events of which morbid growth is the final outcome. But certain alternatives arise here for consideration. Do external factors supply only an initial impulse to growth, which once started continues without their continued influence? This must be true of such environmental factors as chemical or mechanical irritation and radiation. On the other hand, in the case of a concrete agent such as a virus its continued presence may be necessary as a stimulus for the continuance of growth. At the same time when growth begins apparently as the direct result of "irritation" of any kind, it may be that the real effect of this is merely to reduce the cells' resistance to the entry of such an agent as a virus. Again, it is possible though not probable that the modifications which lead to growth may in some cases occur spontaneously, as a mutation in the metabolism of normal cells.

Considerations of this kind are guiding current researches, and knowledge today is fast increasing, not in extent alone but also in precision and significance. As an instance in justification of this claim Sir Gowland Hopkins mentioned the brilliant experimental work during the last few years based on the long-known fact that tar can induce cancerous growths. The combined efforts of the pathologist and organic chemist have shown that it is certain specific substances in tar which are alone responsible for the effects. The exact constitution of these substances is known, while others related to them have been artificially synthesised, and their graded capacity for inducing cancer carefully determined. These cancer-producing substances, though differing from them in details, are akin chemically to substances natural to the body—for instance, to the hormones which control certain of the functions of sex. Indeed it has been shown that in experimental animals subjection to prolonged administration of a sex hormone encourages the growth of glandular cancer, especially cancer of the breast. On the other hand work done in the laboratory of the fund has shown that by the simultaneous administration of yet another hormone this result can be prevented. Such objective facts as these should encourage equally objective and sane thought about a malady which has been so often viewed in the past from a standpoint which was almost that of superstition.

Workers in a centre of experimental activity devoted wholly to one limited end may be in danger, owing to their special preoccupations, of ignoring too much the advances won in other branches of scientific endeavour. These may often contain suggestions and even inspiration which can contribute greatly to the progress of their special task. Frontal attacks alone are proverbially not always the most successful method of dealing with an entrenched enemy. In cancer research this is especially true. Here workers should have liberty and leisure to pursue paths which, though apparently remote from what seems to be the direct one, may prove to be short cuts towards that goal.

In conclusion Sir Gowland Hopkins briefly appraised the present position of the cancer problem and maintained that it shows reasons for much satisfaction.

"With the assurance that fundamental knowledge concerning the actual nature of cancer is continuously increasing, together with the realisation that success in treatment grows with the clinician's increasing skill and equipment, there is surely justification today for an optimistic outlook. It is most desirable, he said, that the lay public should be persuaded to share in such optimism.

JUVENILE AND ADULT CRIME

JOINT CONFERENCE ON DELINQUENCY

THE Magistrates' Association initiated an important step in the scientific study of delinquency by calling a conference, with the cooperation of the British Medical Association, at B M A House on June 23. The object of the conference was to discuss how medical and psychological knowledge could be made available to magistrates in their duties, both in court and elsewhere. The morning session dealt with juvenile and the afternoon with adult crime.

THE MEDICAL OFFICER IN THE JUVENILE COURT

Lord ALNESS presided over the morning session, and after his opening remarks Miss MADELEINE SYMONS, J P, president of the Stamford House Juvenile Court, spoke. Magistrates sitting in the juvenile court, she said, cannot do their work without the help of the medical psychiatrist at the remand home, and of the child-guidance clinics, hospitals and individual doctors who examine children on bail. The practice of remanding for a purely medical examination is growing, but it is necessary to bring home to magistrates the necessity for a simple physical examination in many cases, or otherwise epilepsy, bad eyesight, pregnancy and gross mental deficiency may go undetected. The psychiatric help given to London courts is common sense applied by trained people. The root of the problem is financial: not enough money is spent on remand homes, and for the examination of children on bail the courts have been sponging on the generosity of doctors and charitable organisations. Outside London many courts have no funds to pay for the examination of children on bail. Some of the difficulties, she said, could be smoothed out by clauses 19 and 38 of the Criminal Justice Bill if it becomes law, but a serious omission from the bill is financial provision for the medical examination and treatment of children who are not offenders but who require care and protection, or are beyond control. Adequate medical facilities are also lacking; the passing of the bill into law may stimulate their provision, but a mushroom growth would be undesirable. She hoped that the new act will help in the extension of boarding-out. The vital decision whether the courts want a full physical examination or a report from a psychiatrist in a particular case rests in the hands of lay magistrates. They can only make this decision wisely if with medical help they train themselves to choose the cases which need treatment, and if they can rely on reports from properly trained probation officers who have plenty of time. Miss Symons urged that they should use fully their existing powers of remand.

INDICATIONS FOR SPECIAL MEDICAL EXAMINATION

Dr WILLIAM MOODIE admitted that his remarks would probably be distressing, disturbing and somewhat destructive. A doctor present in court, he said, can give very little help in selecting cases. He cannot pry into a child's soul on the spot and can only detect gross abnormality. He cannot advise the court unless he has a considerable amount of information about the child. Reference for medical examination has in view the best disposal of the child; treatment is far more environmental than personal. The psychiatrist must estimate the intelligence, allowing for "verbal fluency," and decide how far the child is responsible. Delinquents are on the whole, through their hostility

to the world, more backward than other children and do less well in school, so the degree of the child's hostility must be estimated. Without all this and other information about the child and his circumstances, no doctor is justified even in advising the court.

OBSERVATION, DIAGNOSIS AND REPORTS

Dr. J. D. W. PEARCE in dealing with reports on patients in custody, said that remand for special report is no handicap to the examination but rather facilitates it. Remand homes are planned primarily for non-delinquents, the remanded child attends ordinary school classes and takes part in physical drill, games and entertainments, he settles down as at home. In the absence of a history Dr. Pearce's custom is to state the material on which he makes his report. In his opinion for nearly all cases the examining doctor should be a man, as the delinquents are mostly boys and the girls are usually older and will confide more easily in a man. A stripped examination is essential, or important physical disabilities may be missed. The doctor must be in touch with general medicine, familiar with academic psychology and trained in psychiatry, and must be able to mix with patients on the common ground of humanity. He should follow a strict routine. His report must be short, lucid, unambiguous, simple and definite, and he must frankly disclose its deficiencies. He is at liberty to ask for a further remand if he thinks it necessary. Dr. Pearce urged that more child guidance clinics should be established throughout the community, they are the most suitable agencies to do the reporting for the courts.

TREATMENT

Dr. DENIS CARROLL pointed out that the word treatment includes any method of disposing of an offender which a psychiatrist may prescribe. The object must be borne in mind at every stage, and the causes, which are multiple, must all be taken into account. They call for several simultaneous and sometimes contradictory methods of treatment, and the psychiatrist must strike a balance. On the penal side of treatment a doctor rarely has anything to do, but may sometimes advise. Sociological treatment includes Borstal, approved schools, short periods in remand homes, camps, hostels and different kinds of work. Medical treatment must be directed towards organic disease, and the court must use its influence to see that parents facilitate the treatment. Psychological treatment includes suggestion, persuasion and re-education, and sometimes analytical methods. Probation officers who have attended courses on these methods and their aims are doing better work. Superficial causes can be dealt with by psychological and sociological measures, but the deep causes need medical advice and usually also medical attention before the actual treatment.

Prognosis, Dr. Carroll went on, depends partly on age. The younger the offender the better the outlook, but the habit of crime may be a more important factor than the age. The outlook also depends on how bad the mental state is in relation to the delinquency, on defects in the environment, and on the friendliness or hostility of the offender to the people who deal with him. The degree of co-operation he will give can be estimated by practical methods. The Criminal Justice Bill contains the valuable provision that medical treatment may be ordered at any time within three months after the making of the probation order. If this is enacted the doctor will have adequate time to come to a decision. Magistrates and probation officers should receive instruction from the medical angle, for they must form part of a team with the psychiatrist, the psychologist and the social worker. A routine remand in custody is unnecessary and expensive. Most of the children can be dealt with in an outpatient clinic—any psychiatric outpatient department of a general hospital with a children's branch or any child guidance clinic. A court or doctor in doubt where to send a child should write to any clinic in the district, the Child Guidance Council, or the Institute for the Scientific Treatment of Delinquency. Dr. Carroll hoped that the powers proposed to be given by the bill to local authorities to subscribe to voluntary bodies maintaining observation homes or hostels for delinquents will be used if they become law, and that magistrates will press the authorities to provide such inpatient accommodation. If enough cases are referred by the courts, facilities will be forthcoming. The limitation of treatment on a court order to twelve months is bad, and the treatment of some residential cases will collapse if payment is stopped at the end of that time.

DISCUSSION

Several speakers suggested that both male and female doctors should be available for examining delinquents. Mrs. E. G. F. BIRLEY (Manchester) thought that only a woman doctor should examine physically assaulted children, and Dr. HELEN BOYLE remarked that some boys respond more readily to a woman doctor. Dr. PEARCE, however, reminded the conference that few authorities would appoint two examiners, on the ground of expense, and only a small minority need a woman doctor exclusively. Mr. CLAUD MULLINS urged the need for punishment coupled with treatment, and declared that the probation system has been damaged by the exclusion of punishment. A fine may have value in a case where psychological treatment is needed. Dr. CARROLL agreed, with the proviso that treatment will be stultified if the offender is allowed to connect the punishment with it. Dr. R. F. BARBOUR stressed the need for examination in neutral surroundings after two or three days, so that the offender may have time to calm down, the examiner, he said, should see both parents.

Several speakers remarked on the legal difficulty of giving full information to the court before trial, particularly when it contains a statement of previous undetected offences. Dr. CARROLL said that some courts demand that all the information should be given in evidence in front of the offender, but much of the psychiatric information would be very undesirable for him to hear. Severe official comment has been made whenever the contents of reports have been disclosed to the offender, but the critics also apparently demand that the information should be given in the witness box. Mr. ALBERT LIECK (London) said that all relevant information is admissible in the report and that anything adverse to the parents is required by law to be communicated. Miss SYMONS pointed to the statutory rule that the child or parent must be told the substance of such information as relates to the manner in which he is to be dealt with. Magistrates, she thought, should be educated to recognise the kind of information which does harm if communicated to the offender. Mr. MULLINS suggested the possibility of that rule and others being declared ultra vires by the High Court if they were challenged, and no speaker was able to suggest a solution of the difficulty. The medical requirement that the court should have full information on all aspects of the offender's life appears to conflict with the principle

of law that nothing adverse to an accused person should be made known to the court unless he is given an opportunity to rebut it by cross-examination and by evidence on his own behalf

ADULT CRIME

In the afternoon session Mr. GEORGE A. BRYSON (Birmingham), who took the chair, agreed with Mr. Mullins's suggestion of the morning that probation without punishment is beginning to wear thin He said that the problem of deciding which adults are suitable for treatment is even more difficult than that of selecting juvenile cases

Mr. F. J. O CODDINGTON, LL.D (stipendiary magistrate, Bradford), said that the offender who comes before assizes for a serious crime is often remote from the ordinary run of humanity, and he deprecated the cheerfulness with which doctors are apt to report that such persons are not suitable for treatment The adult offender with whom the petty-sessional court has to deal day in and day out, and who makes up the large majority of all adult offenders, is hardly distinguishable from the adult who does not come to court The charges are nearly all concerned with petty theft, minor sexual offences and motoring offences. A large proportion of the accused are first offenders and ordinary, decent people; most of them could be saved from further crime. Mr Coddington said that he sends to prison people he cannot deal with otherwise, and imposes fines in cases where they may be reformatory, especially if payment by instalments is ordered. Medical treatment is chiefly required for elderly first offenders, and for people whose offence is utterly unrelated to their position in life or apparently purposeless. The great variety of ill health and maladjustment in such persons is surprising. Important factors are change of life, pregnancy, epilepsy, arteriosclerosis, general ill health, partial deafness or blindness, and the fear of a strict husband combined with money worries Many women offenders are utterly stale and a holiday works something like a miracle. Sexual maladjustment and loneliness are common factors.

Treatment by medical means, membership of clubs, a talk by the magistrate to the husband, arrangement for the gradual payment of debts, instruction in the elements of sexual hygiene, and similar common-sense measures are, in Mr. Coddington's experience, often successful Petty sexual offenders he nearly always refers to the doctor, and is always able to bind over They are often lonely old men who sometimes suffer from hydrocele or prostatic enlargement, and are reformed by the provision of companionship, the friendship of the probation officer or medical treatment. Young men are often restored to normality by the simplest psychological means · reassurance and an indication of a healthier outlook and way of life Some doctors are incapable of appreciating the requirements of the magistrates, but most of them can be taught. The courts want a medical examination followed by a common-sense discussion from the psychological—not the psycho-analytical—point of view Treatment, he maintained, should be planned from the medical and not the theological aspect Delinquents respond to the fact that they are being treated medically and not punitively.

Prof F. W. EURICH, to whom Mr Coddington paid a warm tribute as his medical ally for many years in dealing with delinquents, said that an offender's obstructiveness soon disappears when he finds that the doctor has nothing to do with the criminal proceedings and that the magistrate only desires to help him. The doctor must study man as a whole and not confine himself to the psychological, or even to the medical, angle. Several obscure ailments may cause delinquency—e g, hypoglycæmia, a thyroid growth, or constipation of organic origin. Apparent drunkenness in charge of a car may well be due to mild carbon-monoxide poisoning.

THE MEDICAL PSYCHOLOGIST AND THE COURT

Dr. J. R. REES put forward a classification of mental abnormalities connected with delinquency He said that investigation by the Tavistock Clinic has shown that over half its adult cases are free from crime after three years Reaction character traits are the hardest conditions to alleviate, and the psycho-neurotic delinquencies, inconsistent with the offender's ordinary culture and training, have the most hopeful prognosis He suggested that a good beginning would be to encourage every court to send for psychological help all people who commit sexual offences or irrational acts, or who repeat offences. Fewer facilities are available for treating adult than child delinquents, but local-authority clinics will improve rapidly Intuitive diagnosis is untrustworthy unless founded on a long practical experience of psychopathology Expansion must be slow, and for some time the courts will have to be content with sound diagnosis and advice on treatment A full treatment service is costly and cannot be organised quickly The court should institute follow-up investigation for research into the value of treatment

In discussing the afternoon's papers, Mr. MULLINS pointed to the grave difficulty that, outside London and the big cities, most delinquents are sentenced within a few minutes of the ascertainment of their guilt, and a remand for inquiry is unusual Assizes and quarter sessions can only adjourn the case to their next sitting, which may be months in the future Public opinion and the authorities must have impressed on them the need of time for proper inquiry between verdict and sentence Only medical men can bring this need home Dr REES, on being asked what provision is being made for the training of medical officers for outpatient clinics in the country, said that the Institute for the Scientific Treatment of Delinquency holds week-end courses and lectures, the Tavistock Clinic gives two-year and shorter courses for psychotherapists; and the Maudsley Hospital provides lectures for the diagnosis but not the treatment of delinquency. If the new act results in enough remunerative work being available for these officers, he said that a supply will soon be forthcoming—especially if, at the same time, steps are taken to encourage young medical practitioners to take up psychotherapy in the provinces At present no great inducement is offered to the newly qualified person to train in psychotherapy.

The conference resolved to recommend to the Magistrates' Association and the B.M.A. that a small joint standing committee should be established to further the coöperation of magistrates and doctors in the treatment of delinquency.

ELECTRONIC REACTIONS AND DIPHTHERIA.—The adjourned inquest at Leigh, Lancashire, on the boy who died from diphtheria after having been attended by Mr C C. Abbott, an unqualified practitioner who made his diagnoses on electronic reactions, was concluded on June 21 (see *Lancet*, June 24, p. 1457). After an absence of an hour the jury returned a verdict of death by misadventure.

THE LISTER INSTITUTE

CLINICIANS reading the whole of this year's annual report from the Lister Institute of Preventive Medicine will find themselves travelling far from the bedside Sometimes it is the distant journey—the apparently remote investigation—that discovers the biggest treasure, whether for the cure or the prevention of disease In a brief review of the year's work, however, we can mention only those of the institute's inquiries that have an immediate bearing on medicine or health, and, indeed, only a few of these

VIRUSES

Acute rheumatism and rheumatoid arthritis—Dr G H Eagles has continued his studies on the etiology of rheumatic infections Attempts to demonstrate the infective power of the virus like particles procurable by high speed centrifugation of exudates and tissues from rheumatic patients have failed In *collaboration* with Dr W H Bradley, however, he has demonstrated that the sera of patients with rheumatic fever, rheumatoid arthritis and certain other arthropathies agglutinate such particles, whereas sera from persons in normal health do not No consistent relation of agglutination to clinical phases was found, nor any evidence that it runs parallel to antistreptolysin titre or erythrocyte sedimentation rate

Acute rheumatism and the pleuropneumonia group of organisms—Homer Swift and Brown, of the Rockefeller Institute, have recently announced the isolation of a pleuropneumonia like organism from rheumatic fever exudates (see *Lancet*, April 22, 1939, p 938), and this may prove to be the long sought *etiological* agent of acute rheumatism In any case the finding opens up a new field and already Dr Eagles and Dr Helga Jahn are collaborating with Miss E Kleneberger, Ph D, in the cultural study of rheumatic material Should *organisms of this group* be recovered steps will be taken to determine whether the "virus bodies" studied at the institute by Dr C R Amies and Dr Eagles, which are agglutinated in the presence of sera from rheumatic fever and rheumatoid arthritis, are really the filtrable elements of a pleuropneumonia like organism, or possibly breakdown products antigenically related to such organism

Avian sarcoma—Dr Amies and Mr J G Carr, working on the filtrable agents of the Rous I and other fowl sarcomas, report that it has lately become possible to obtain adequate amounts of these agents in a relatively pure form—i e, in suspensions containing 1,000,000 tumour producing doses per c cm Serological experiments with these concentrated suspensions have yielded still more evidence that the agent is closely related antigenically to some constituent of normal fowl cells It has been established, for example, that the serum of a rabbit hyperimmunised with normal fowl protein will neutralise the tumour agent in vitro, and that these inhibiting properties can be removed by absorption with a concentrated suspension of the tumour agent In the fowl, the agent behaves as a foreign protein because its presence in the malignant tissue and elsewhere elicits the formation of neutralising antibodies and agglutinins It is believed that a full understanding of this phenomenon would constitute a big advance

Smallpox vaccination with elementary body suspensions—In cooperation with Dr R G Henderson and other officers of the London County Council, Dr D McClean (Elstree) has continued the experimental immunisation of nurses and children by intradermal injection of elementary body suspensions of vaccinia virus The resulting immunity, as tested by revaccination with Government lymph after not less than six weeks, has proved disappointing, and there is some indication that the development of a firm immunity depends on the development of a typical vaccinal vesicle at the primary vaccination When applied by scarification, the suspension of elementary bodies produces typical vaccinal vesicles with general constitutional reactions indistinguishable from those produced by vaccine lymph

SEROLOGICAL STUDIES

Antityphoid serum—Mr A Felix, D Sc, with the assistance of Miss R M Pitt has continued his investigations on methods of titrating therapeutic antityphoid serum The Vi titres of the sera, as determined by the agglutination reaction, run parallel with their protective values as determined by tests in mice which received a test dose of living virulent typhoid bacilli The O titres of the sera, as estimated by the agglutination reaction, run parallel with their protective values as determined by neutralisation tests in mice which received a lethal dose of killed typhoid bacilli ("endotoxin") Provided it is known that the Vi antibody in the sera does not exhibit the peculiar "functional deficiency" described by Felix and Bhatnagar in 1935, the Vi agglutinin titre as well as the O agglutinin titre can be accepted as the final measure of the therapeutic activities of the two antibodies The routine titration of samples of serum taken in the course of preparation of therapeutic antityphoid sera consists, therefore, in agglutination tests alone

Dr D W Henderson (Elstree) finds that the Vi or the O antibody will protect mice against infection with a fully virulent Vi+O strain of *Bact typhosum*, but when a large number of fatal doses are given the Vi antibody is relatively more efficient than the O antibody

Prophylactic inoculation during a typhoid epidemic—The desirability of carrying out vaccination in a population exposed to typhoid infection has been questioned on the ground that undesirable reactions may intervene, followed perhaps by frank disease in persons harbouring the causative organisms Such persons may be incubating the disease—in which case vaccination may, it is said, accelerate the onset of symptoms—or they may be temporary carriers until vaccination converts their state into one of frank infection Correspondence on this subject appeared in the medical press, two years ago, in the light of advice tendered to authorities concerned with the control of a typhoid outbreak (*Lancet*, 1937, 2, 1319, 1402, 1454) In an attempt to find an answer Dr H L Schütze has taken the mouse as the experimental animal and *Salmonella typhi murium* as the infecting organism The results of a large series of experiments demonstrate, he holds, not only that vaccination started after infection does not damage the animal's normal resistance, but that in a considerable proportion of cases it actually enhances it

Plague—Dr Schütze, investigating the effect on plague infection of M & B 693, Solseptasine, and a diamino diphenylsulphone glucoside, observed a considerable curative effect on the part of all three compounds M & B 693 proved most efficacious against plague in both rats and mice, solseptasine protected rats and not mice, and the sulphone compound protected mice but not rats (*Lancet*, Feb 4, 1939, p 266)

SERUM-PROTEINS IN HEALTH AND DISEASE

Mr. R. A. Kekwick has continued his work on the behaviour in the ultracentrifuge and electrophoresis apparatus of normal and pathological serum. The electrophoretic constitution of normal human serum has been established and shown to differ fundamentally from the picture obtained with sera from cases of multiple myeloma, kala-azar, and acute rheumatism. The abnormalities found in the protein constitution of these pathological sera were well marked and consistent for a given disease. It is not possible to say how specific they are until a wider pathological field has been investigated.

ENDOCRINOLOGY

Dr. V. Korenchevsky, with the assistance of Miss K. Hall, Mr. R. C. Burbank and Miss M. A. Ross, has further examined the activity of sex hormones in the rat.

Effect on senility.—Testosterone propionate, he finds, can produce in senile rats even supernormal development of the sex organs, but it does not cause any noticeable improvement in their appearance and behaviour. As these organs and sexual function may be well preserved in otherwise senile animals and men, the absence of a "rejuvenating" effect of the sex hormones is held to be not surprising. The over-stimulation of the secondary sex organs of senile rats by testosterone propionate cannot be regarded as a rejuvenating effect, since, without simultaneous improvement of the general condition, this sex stimulation is biologically unnatural "and in human patients is medically undesirable." Moreover, the administration of testosterone propionate depressed the development of the sex glands of the senile rats, thus checking the secretion of the natural sex hormones by the testes. The development of the sex organs may be stimulated or depressed by some of the male hormones according to the dose injected.

Tumours were found in the hypophyses of two of the injected senile rats.

Sex hormones with prolonged activity.—Recently enol and aliphatic esters of sex hormones have been prepared, chiefly by Swiss scientists. The most important feature of these esters is their prolonged activity after the cessation of the injections. With certain of the doses used the maximum effect of testosterone dipropionate and œstradiol dipropionate was maintained for at least 10 days, and that of œstradiol benzoate-butyrate for more than 106 days, after discontinuation of the injections.

"*Precancerous œstrogenic changes*"—Injections of œstradiol dipropionate are followed, it is stated, by development in the uterus of metaplastic changes in the epithelium, which are the first stage of a precancerous condition. This develops more frequently, or in more severe form, when androsterone, *trans*-dehydroandrosterone and testosterone dipropionate are injected with the œstrogens. On the other hand, progesterone and (when injected in a special ratio to œstradiol) testosterone propionate can prevent the precancerous changes.

ACCESSORY FOOD FACTORS

Progress is recorded in the work of standardising vitamins A, B_1, and E, in the investigation of the B_2 factors, and in the study of pellagra and related disorders of animals.

Vitamin-C requirements of man.—Mr. S. S. Zilva, D.Sc., and Dr. A. E. Kellie have finished an investigation in which the minimum daily dose required to maintain an adult "saturated" in respect to vitamin C was ascertained. Equilibrium of excretion was established on doses of 100 mg., 50 mg. and 30 mg., and the minimum "saturation" dose was found to be in the neighbourhood of the last figure. Previous investigations on animals suggested however that a daily dose of about half the "saturation" dose is sufficient to meet the theoretical requirements of man. The ascorbic-acid content of the blood was determined during "saturation" and "unsaturation" at different intervals after the administration of the vitamin in various doses. The comparison of these figures with those of the urinary excretion suggests that there is no constant renal threshold for ascorbic acid, but that there is a competition for the ascorbic acid of the blood by the absorptive capacity of the tissues and the excreting function of the kidney. Blood levels determined at random do not, therefore, indicate the degree of "saturation."

Vitamin C in vegetables and fruits.—Dr. Zilva, collaborating in an investigation of the ascorbic-acid content of King Edward VII potatoes lifted from the soil at various stages of development, and of the decline in vitamin-C concentration during storage, reports that the content reached a maximum at the third lifting, in early September. On storage at 10° C. the potatoes lifted in October lost the vitamin rapidly at first but later more gradually. The fall in samples lifted before October—i.e., the normal time of lifting—was strikingly greater.

To ascertain the effect of storage on vitamin C in canned apples, samples canned early in 1935 and tested in 1936 were re-examined in 1938. A 50 per cent. loss was recorded, previous intermediate tests had shown this to be progressive.

TYPE CULTURES

The National Collection of Type Cultures (Medical Research Council) has continued to expand. Some 6300 cultures of micro-organisms have been distributed during the year to workers at home and abroad and many new strains have been deposited for maintenance. A new and revised report on the genus salmonella will be presented to the nomenclature committee of the International Association of Microbiologists at the International Congress for Microbiology to be held in New York this autumn. The report is being prepared by the salmonella subcommittee, of which Dr. R. St. John-Brooks, curator of the collection, is secretary.

THE LANCET 100 YEARS AGO

June 29, 1839, p. 514.

From a leading article

A KNOWLEDGE of nature is obtained in two ways,—by observation, and by experiment. *Physicum id est speculatorem, venatoremque naturæ*, says CICERO. We observe, record, and determine the relations of natural phenomena, or we produce effects in order to determine their relations and causes. The experimental sciences, and the sciences of observation are, however, identical, for it is indifferent whether physical phenomena occur spontaneously, or are artificially produced, so far as regards the determination of their laws. But experimental investigation is often more attractive than observation. The observer is a sentinel, a looker-on, or, at the most, a watchman upon the lofty towers of nature, the experimenter, on the contrary, is animated by the pursuit of his game, his blood is heated, his hopes are on the stretch, the forms of truth fly and double, appear and disappear, before the hunter's aching eyes, and the pleasure of the chase is as thrilling as that of the capture. How many have lived and died happy in the search after ideal objects—for instance, the philosopher's stone and the elixir of life!

GRAINS AND SCRUPLES

Under this heading appear week by week the unfettered thoughts of doctors in various occupations Each contributor is responsible for the section for a month, his name can be seen later in the half-yearly index

FROM A WOMAN PUBLIC HEALTH OFFICER

I

THERE is a mocking Gaelic proverb which has ornamented my desk for some years It runs "He is a good hurler,* is the man on the fence" I love it partly for the salutary warning it holds for the bureaucrat and partly for the picture it evokes One can feel the wet Irish wind on one's face, and hear the clashing of the hurley sticks, while the excited lad on the fence nearly topples off as he shrieks valueless advice at the straining players One suspects, too, that the reason the man is on the fence and not in the team is just because he isn't good enough Some day if he isn't careful fate may play him a nasty trick and bring him down from his perch, thrust a hurley stick into his hand, and bid him get on with the game himself Even so do I find myself a dispenser and no longer a critic of Grains and Scruples

* * *

It is a queer business this of turning over the garnered store of nearly forty years to find some thing worthy of being shared with colleagues known and unknown A man's most treasured possessions too often seem like junk to the stranger's eye, and his deepest convictions mere infantile prejudices At this singularly gloomy phase of the world's history when the sky is black with "intimations of mortality" the only sensible advice is that of the evangelical hymn "Count your blessings one by one" Looking back, perhaps the first of these for the young medical student was the contact made at the very outset of one's career with great teachers and great traditions Perhaps doctors do not always realise that in this respect they are privileged beyond the entrants to other professions That our best men spend so much time in teaching kindergarten has some regrettable results but no other system could spread so widely the riches of their minds and personalities

The arrangement of the curriculum (which I do not intend to discuss) has no doubt improved immensely in recent years but I doubt if the present day hierarchy of the profession provides as generous a feast for the observant young as did the professors at my own Scottish university We still retained the Victorian tradition of highly developed individuality The pride and joy of the school was a famous authority on forensic medicine equally beloved for the rareness of his lectures and for his discrimination as an examiner He had an infallible method, worthy of wider imitation, for reassuring a nervous student On the examination table stood the usual row of evil smelling little bottles containing material to be "spotted" As the tongue tied one hesitated the kindly old gentleman, hero of a hundred *causes célèbres*, absentmindedly rotated the bottle so that the label came to the front It was said that after a myopic youth had nearly defeated him he always kept a bottle of copper sulphate crystals in reserve for desperate cases Only once did he fail below his own high standard Asked to explain his eccentric marking of a brilliant paper presented by a woman student, daughter of a colleague, he is said to have retorted fiercely, "Well he ploughed my son and by gad, I'll plough his daughter"—but quickly repented Thanks to that generous heart, no police man's form ever darkened the wards of our great infirmary, Sir Henry thought the suggestion of punishment an outrage on the sick and bullied the authorities into compliance, cheerily regardless of not infrequent escapes

The women students at least were ready enough to welcome the police as escorts of outpatients In the cramped little casualty room which was all the territory allotted to us, they subdued our patients' lurid language, taught us how to handle a razor, and told us thrilling stories of the underworld while we stitched cut heads In those days of cheap whisky one expected most casualties to be drunk, and I can recall a New Year's Day when of 82 accident cases only the first 20 were even approximately sober The police, who knew the sordid background of their lives, gave us our first lessons in tolerance

* * *

To return to the more orthodox instructors, many of the great folk round us remained merely names, for the women were kept under as near an approach to the purdah system as a mixed school permits We were forbidden university lectures, and for clinical teaching were restricted to the wards of the junior surgeon and physician on the staff who had each to put in a purgatorial five years teaching the interloping sex But we could afford to chuckle at the way things turned out A system that gave us Professor Caird in surgery and Sir Robert Philip in medicine left no resentment Caird was a man whose personality should surely be recorded, to inspire other generations as he inspired ours A magnificent teacher of his subject, he was also supremely successful in conveying lessons that the surgeon can impress on students' minds as no one else can Meticulous care in examining and recording the simplest case, and a beautiful courtesy and consideration for patients were part of the routine of his wards Later, experience in provincial hospitals opened one's eyes to the different standards which existed and I imagine still exist in this respect It is the sort of thing that in any hospital or institution percolates from above down

We had luck of another sort in the midwifery lecturer, Dr Ballantyne Not that he was much of a lecturer, for only too rarely did he allow his pawky sense of humour or his undoubted vision to overflow into the rather dreary discourses he delivered in the Surgeon's Hall But one day he abandoned his notes and very shyly confided in his class of some 18 young women his dreams for easing the burden of pregnancy, for making delivery safer by intelligent preparation, for giving the infant a better chance by caring for it throughout gestation It was a new gospel at the dawn of the century, the class was moved to break into unexpected cheers—and Dr Ballantyne blushed and retired into his shell Later he told some of us that he was meeting with little support from many of his obstetrical colleagues who thought that ante natal care even for private patients was dangerously fussy. The notion that it should be available for *all* women had to wait for a concomitant development of the social health services, in the same

* Hurley is the Irish version of hockey

that the aeroplane had to wait for the invention of the internal-combustion engine.

Dr. Ballantyne could get back neatly on some of his critics and I have heard him relate—in private—the following tale. An Eminent Obstetrician who had been engaged for the confinement of a Great Lady, received the call to her bedside towards the conclusion of a very festive dinner Some inward voice told him it might be wiser to send his assistant but he reflected that the latter was a pushing young fellow and anyway the smell of chloroform *à la reine* covers a multitude of other odours Everything went swimmingly It was one of those ideal cases where nature—i.e., the mother and maternity nurse—does all the work True, the baby was on the small side, but it was of the right sex and the mother seemed more than satisfied. The eminent obstetrician felt fully justified in hastening off to a bed that every moment appeared more desirable, but had only reached the foot of the front doorsteps when he heard his name called. He looked up and saw the nurse grimly regarding him from the doorway, "Well, nurse, have you forgotten anything?" he asked impatiently "No, Sir, but I thocht mebbe you had the twin"

* * *

Not even a desire to compensate for the news on the wireless could however persuade me that if the hands of the clock could be turned back all would be well Entrants to the nursing profession may be scarce now, but I should hate to see them plentiful—and bullied and overworked and underfed as they were thirty years ago Again, over-specialisation may be the curse of the profession, but from the patients' point of view its absence is still more to be deplored. In all that great Scottish infirmary there was no anæsthetist; all anæsthetics were given by students, taught only by their seniors and equipped with a folded towel, a gag and tongue forceps, two safety-pins and a bottle (unmeasured) of chloroform. If a surgeon found (as Mr. Caird once did) during the vacation that his list included an excision of thyroid, a carcinoma of the breast, and an excision of the kidney and the only student on duty was a girl of 19 in her second year, they both went ahead without comment. The results were astonishingly good, but I always felt that the guardian angels of all concerned were being tried rather high.

The chief difference on the debit side, however, was the complete lack of social services, of aftercare to consolidate the good work done in the wards, and of the *preventive* outlook generally You will still hear modern advances spoken of as though they were an unprovoked attack on an ideal system of private practice. One remembers how much of the illness one saw was due to deficient nourishment and to an inconceivable filth of hair and person. The only preventive measure that occurred to anyone was to blame the unfortunate mothers or to proffer them lordly advice on a matter on which none of us, male or female, had the slightest experience—i.e., running a working-class home on a working-man's income I count it not least of our blessings today that the working-woman is no longer a bundle of squalid rags surrounded by rachitic and verminous children.

* * *

A batch of papers from a college for "nursery nurses" has just come in for correction Written in clear round hand this statement catches my eye "The skin contains salacious glands . . . and censory nerves." How wise are the dispensations of providence

PUBLIC HEALTH

School Medicine in Manchester

In an introduction to his valedictory report to the Manchester education committee Dr Henry Herd discusses briefly the two chief contentions with which his name is associated—the relations of the school medical officer with the public-health service and education department, and the place of routine inspections in the medical supervision of school-children. Manchester is one of the few localities where the medical officer of health is not the school medical officer, the latter being appointed by the education committee and having no official connexion with the health office But in most large local units the executive school medical officer, though nominally an assistant, is largely independent of the medical officer of health who contents himself with coördination of the school service with the rest of his department So in practice it makes little difference whether or not the school medical officer is independent of the medical officer of health, provided that there is complete cohesion between the two officers, and in recent years this has been generally achieved Unless there is close coöperation between school medicine and child welfare reduplication of effort occurs, the children lose continuity of supervision and many matters which should be remedied in infancy are deferred until school age. Moreover, the health of children attending school is much influenced by the variations of infectious diseases; the school officer must be in touch with the officer whose chief function is epidemiology On the other hand, school medicine is intimately connected with education. As Dr. Herd says, "the school medical service can never be a purely medical service, but must be very closely identified with the general educational service" The bond between school medicine and general education grows closer, as the fitting of abnormal children to their educational environment is becoming the chief work of the school medical officer.

Dr Herd has for several years urged reform of the system of routine medical inspections At the congress of the Royal Sanitary Institute, held in Bournemouth in 1935, he was one of the leaders of the reform party which sought to replace routine inspections at fixed times by more general inspections of all children at shorter intervals and continuous supervision of those who were defective, or whose health or normality was doubtful The case of the reformers is very strong, although for their system to be successful more labour and greater skill are required than can be commanded everywhere The Board of Education makes routine inspections the cardinal point of school medicine, those who think with Dr Herd look upon them merely as adjuncts to continuous supervision In districts where the school department is properly staffed all that Dr Herd advocates could be obtained without abolishing any of the routine inspections—to a large extent he has himself achieved it

The records of the school medical department of Manchester do not differ materially from those of other cities There has been the same steady improvement in the health and physique of the children, similar increased attention to matters formerly considered to be of minor importance, and an increase in the

quality and expedition of treatment for those children who need it In Manchester a definite improvement is shown in children as they grow older of the entrants 22 8 per cent required treatment, of the twelve year old group only 14 7 per cent Most of the conditions calling for treatment were either trivial blemishes, physiological deviations, or minor ailments to which little attention was paid before the development of school medicine The most important purely medical work of the school department is in connexion with abnormal conditions of the upper respiratory tract These include tonsils, adenoids, enlarged glands, nasal catarrhs, and otorrhœa There was a time when all manner of evils were attributed to adenoids and the T & A operation was regarded as the remedy It is now agreed that upper respiratory catarrh is a highly complex matter, involving many factors and calling for many forms of treatment, amongst which removal of adenoids or tonsils or both still occupies an important place Otorrhœa and nasal catarrh, though they have diminished greatly in frequency, are still amongst the chief worries of the school medical officer To Dr Herd and his generation, acting with throat specialists attached to the school department, we owe most of our present knowledge of upper respiratory catarrh at school age In this report much space is given to throat and nose defects, including an account by Mr Brian Robinson of the results of dissolvation, which should be read by all who are not familiar with this form of treatment

During Dr Herd's tenure of office great advances have been made in child guidance, and, in coöperation with the physiological department of Manchester University, work has been done in genetics and physiological variations which are gradually changing the outlook of school medicine When he started the chief work of the school doctor was to detect and obtain treatment for children suffering from diseases and defects which should have been detected and treated before, his main work has shifted to fitting to their environment individual children deviating from normal

PARLIAMENTARY INTELLIGENCE

ON THE FLOOR OF THE HOUSE

By MEDICUS, M P.

THIS week has been remarkable for two defeats of the Chancellor of the Exchequer The first defeat was one by negotiation, that in which the Chancellor withdrew the duty on films The explanation then was that it had not been possible, because of the need for secrecy in all Budget arrangements, to consult the trade and that an error of calculation had been made Perhaps But on this the House remained slightly sceptical Whatever the reason however the withdrawal of the duty a defeat by negotiation, happened The second defeat was a defeat by argument and organisation inside the House of Commons The Chancellor had proposed to repeal the duties on patent medicines and the excise licence but had not proposed to control the sale of patent medicines or appliances or any of the preparations which come within the description of proprietary medicines in any alternative way The duty was to be repealed and the field left open without any attempt at control This proposal attracted a great deal of attention as soon as it was known after the Chancellor had made his Budget speech The Medical Parliamentary Committee considered the matter and its members, who belong to all parties in the House, consulted with their friends as to what was likely to be the outcome of this proposal

It was agreed of course that the duties were archaic and in need of revision A select committee of Members of the House of Commons had reported in that sense as lately as 1937 But this committee, which was unanimous, proposed an alternative method of taxation and a further control not only of medicines but such apparatus as deaf-aids and such substances as quasi medicinal beverages and quasi nutritious foods To have the whole of these very carefully considered recommendations brushed on one side was more than the members of the select committee could stomach

In a very short time it became clear that a large body of opinion in the House of Commons was opposed to the repeal of the patent medicine duties unless they were replaced by some alternative method of control The existing amount of control by taxation and licence is not great but to repeal the duties would have thrown the patent medicine trade wide open The pharmaceutical chemists had also considered the question and they added their influence to the persuasions of the already informed members of the House of Commons, and, at a later stage, circularised all members and pointed out, among other things, that in case of repeal of the duties "unless some further change in the law is made any person or persons can, from September next, make and supply medicines to the public through any vendor or automatic machine, without disclosing the composition of the medicine sold This will most likely result in a great increase of so called cures of unknown content for self medication, which would constitute a grave public danger"

The pharmaceutical organisations and individual chemists were not, however, the origin of the opposition to this repeal They came indeed fairly late into the field It was organisation inside the House of Commons by the Medical Parliamentary Committee and the members of the select committee that started the ball rolling By Thursday, June 22, when the Finance Bill came up for discussion in committee of the House, opposition to the duties had so hardened that as many as 200 supporters of the Government, led by Sir Francis Fremantle, were asking for the postponement of the repeal for some years—which was of course equivalent to rejection Another amendment, put down by Mr Lewis Silkin and Dr Haden Guest of the Labour Party and Mr Gwilym Lloyd George, Mr Graham White and Sir Percy Harris for the Liberal Party, was supported by over 50 names, and there was only a small minority of members in either opposition party who were in favour of repeal. The remarkable situation was presented of a large proportion of members of all parties being against the abolition of a tax—quite contrary to usual parliamentary procedure But up to the actual time of the debate on Thursday evening—which was, unfortunately for purposes of press publicity, at a very late hour—the Chancellor had given no indication of his attitude

* * *

The attack was launched by Mr Graham White for the Liberal Party, who recalled that on the second reading of the Finance Bill the opinion of the House appeared to be against repeal and said that the more

he considered the matter "the more inadequate" seemed the reasons advanced for the abolition of the duties Mr Graham White had hoped we were moving towards the adoption of a nation-wide medical service but the proposed repeal was an attack on the national health service; and he recalled how the Ministry of Health had deplored the use of advertisements and quack remedies in connexion with cancer. The Chancellor of the Exchequer would, however, open the way to the sale of any nostrums or quack remedies Sir Arnold Wilson, who was a member of the select committee which reported in 1937, urged retention of the duties for a further period of at least one year in order to replace them by "something better and more effective." There was no reason for precipitant action as the duties had "been going for 100-odd years and can very well go on for another year"; meanwhile the Chancellor would be "in a position to reconsider the whole thing in all its bearings, which are much wider than those merely of the revenue" Sir Arnold Wilson saw no objection to taxing proprietary medicaments and preparations, "whether medicinal or quasi-nutritive, whether aids to beauty or to health, to sleep or to relieve pain" If the duties were repealed, he said, we should be "the only country in Europe and almost the only country in the world except the United States . . . where patent medicines and proprietary medicines are not taxed" It appeared that alternative schemes had not been discussed with representative interests and some of the largest druggists in the country had said they were not consulted The National Pharmaceutical Union and the Pharmaceutical Society of Great Britain were not consulted The point in Sir Arnold Wilson's admirable speech which attracted most attention was that in which he quoted the Chancellor as saying: "Not only are the present duties unworkable—they are being worked unlawfully and our action has been challenged," and he recalled that the firm which had thrown down this challenge was F. W Woolworth & Co., whose managing director appeared before the select committee to give evidence "The managing director said he wanted to sell more drugs, and he could sell far greater quantities in 2*d*. or 3*d*. packets than in 6*d* packets and the stamp duty prevented him selling his smaller quantities." If it was necessary to meet this challenge of an action for damages Sir Arnold said "many of us" would have preferred to see the Government lose the action The situation could have been dealt with by retrospective legislation, because, although this course is disliked, in principle if anyone in the country "puts a pistol to the Chancellor's head, we would willingly come to his support" Sir Arnold considered that if the taxation of cosmetics was added to that of medicines the duty would bring in from 3 to 5 millions, an important amount of revenue, and taxation would facilitate control.

Dr. Haden Guest dealt with the matter entirely from the health point of view and described the proposed repeal as "an attack upon the health of the people" It would be a grave injury to health although of tremendous advantage to certain large interests The proposal to repeal was received "with a whoop of joy" by certain circles in the city. There had been some big financial flotations and "inflations of a really disgraceful character in the patent medicine racket" in recent years. There is a great amount of money in the trade; the select committee calculated it at £20,000,000 a year on a moderate estimate and it was a trade built up, in the words of the select committee, "by making the people, largely the poor and less well educated, spend more money than they can afford on remedies of little or no efficacy with an accompanying indirect danger to health as a result of their not seeking medical and surgical treatment in time" It was a trade based "on an appeal to fear." Dr. Guest proposed that if the Government persisted in the repeal the Government front bench should give "an unequivocal undertaking and understanding that they will bring forward legislation to control the whole of the patent-medicine and patent-instrument industry"

The debate was one very largely in the hands of the medical M.P.s, the two next speakers both being doctors. Sir Henry Morris-Jones urged the Chancellor to give way to the arguments which "represent a very strong feeling in the country" and he was mystified as to why, at this time, the Exchequer should "throw away a matter of £1,000,000 a year" in taxation.

Dr. Edith Summerskill agreed with Sir Henry across the floor of the House and said that if the Chancellor repealed the duties "he will be aiding and abetting a gigantic swindle throughout the country," and she gave examples of the constituents of certain patent or proprietary medicines. She asked the House to imagine what would happen "when the whole market is flooded with these people, who are just waiting to deceive." No one spoke for the Chancellor until Mr. A. V Alexander of the coöperative movement, and he was lukewarm as he said the cooperative societies "had always been against the wide advertisement of worthless remedies." The House however, including the Labour Party, was so impatient of Mr. Alexander's tepid support that he had to reply to an interruption by saying "I hope the Committee are prepared to listen," and there was a good deal of interruption later.

Sir John Simon to conclude the debate made a half-hour speech of exposition of the reasons which had led him to propose the repeal of the duties and referred to "the existing bungle of ancient statutes on this subject" which were "little more than a lot of incomprehensible irrelevancies." The Chancellor was subjected to a number of questions on his speech, by Sir Francis Fremantle, Sir Arnold Wilson, Mr Latham, a member of the select committee, and others. But the victory of the House, led by medical opinion, over the Chancellor was signified when he said that the sense of the committee evidently was that they would like to get some new treatment of the problem of patent and proprietary medicines combined with the repeal of the duties. "I have no doubt," he said, "that is the feeling of a very large part of the committee I do not myself feel at all confident that that can be done." The Chancellor then announced that he would be willing to maintain the duties for another year with a view to reconsideration of the whole position.

* * *

The debate was a notable one, but a debate which finishes after half past eleven even although very lively does not get well reported in the daily press But the debate showed the influence of well-informed opinion outside the front bench circles The vote was left as a "free" vote by the Labour Party, and the Government whips were quite unable to get their supporters to vote for the Chancellor on this occasion Danger remains however, for an "industry" that at a moderate estimate is worth £20,000,000 a year is a very big vested interest. It is fortunate therefore that the medical and pharmaceutical professions have shown themselves so much alive to the public-health aspects of these duties and that members of

the House of Commons have shown themselves willing and able to take independent action The general conclusion, among members of all parties of the House after the debate, was that it was a glorious victory for democratic institutions As one member put it, "the House just would not have the repeal of these duties"

FROM THE PRESS GALLERY

The Decline in Population

In the House of Lords on June 21 Viscount SAMUEL called attention to the prospective decline in the population, which was causing widespread concern In the age of Malthus the great problem was how to check the increase of population, now the situation was entirely changed While the production of foodstuffs and other commodities had vastly increased, the means had been discovered to control the birth-rate, and the increase in population would soon be replaced by a decrease It was not enough merely to take the crude birth rates and death rates of the population and compare them, the future depended on the age-constitution of the population and on other factors The chief point, he said, for consideration was the number of live births per thousand women of possible childbearing age, taken as being from 15 to 45 In 1891 this number was 109 8 in England and Wales At the last census in 1931 it had fallen to 64 3 In the 'nineties one out of every four women between these ages would give birth to a child in any particular year, as against only one in eight in the 1930's That was a remarkable and unprecedented change not spread over centuries, but taking place in the course of a single generation There had been, of course, some counterbalancing factors The death-rate had fallen greatly, though not so greatly as the birth rate In 1891 the rate was 19 7 per thousand, now it was about 12 4 In particular the *infantile* death-rate had fallen with great rapidity During the present century the strenuous efforts by the state, local authorities, social workers and the medical profession to reduce the death rate had had a phenomenal success In 1901, when this movement really began to take effect, the number of infants under twelve months who died was 140,000, or one in seven of all the births of that year Now the number had been reduced to 35,000, or one in sixteen of the births That was to say that 100,000 babies who would have died in the previous generation were now saved Another counterbalancing factor was the fact that instead of people emigrating in thousands to the Dominions, the United States and elsewhere, there was an inward movement on balance of 20,000–30,000 people But these factors were far from counterbalancing the fall in the birth-rate

ECONOMIC AND STRATEGICAL RESULTS

Various hypothetical estimates had been made, Lord Samuel continued, of the result of these trends if continued into the future Dr Laybourne had concluded that by 1970 the population of England and Wales would be reduced from 41 million to 30 million Another estimate by Dr Charles showed that the actual decline would begin in 1941, and that at the end of this century the population would be reduced by half Of that reduced population nearly half would be over sixty These calculations might prove wrong, *but they demanded* immediate attention Some thought that this country was overpopulated, and that it would be no bad thing if we were reduced even to 20 million But the truth was not that this island was overpopulated, but that its population was badly distributed Overcrowding in England was far worse in the 19th century, with a smaller population, than it was today From the economic point of view a decline in population must mean a great diminution in productive power Again some held that because there were 1½ million unemployed the country must be overpopulated, and that if our population were reduced by that number, we should get rid of the unemployment In the 19th century, when the population of England and Wales was 10–15 million, there were periods of terrible unemployment and distress, whereas in the year before the late war, when the population was 36 million, everyone was employed It was obvious how grave would be the effect on revenue if the number of producers and taxpayers were seriously reduced, and the burden of pensions for an older population, and the heavy charge of debt which was being handed on to posterity, could hardly be borne by a greatly diminished population There was also the strategic aspect The man-power of a nation was an essential element in preserving its position in the world Unless the tide of emigration could be again enabled to flow England would not be rendering the service to the world she was able to do in previous generations

ITS ÆTIOLOGY AND TREATMENT

The causes of the decline, which was not limited to Great Britain, were due to no physiological change in the human race but to deliberate conscious human action Children were not born because prospective parents did not wish them to be born, and had found means to prevent conception without forgoing marriage or intercourse The reason for this state of affairs was largely economic—poverty, or the fear of poverty Furthermore, parents had to consider the interests of the children they already had from the point of view of nutrition, education and general prospects There was also the question of housing Among the non-economic reasons was the health of the mother, which was prominent in the minds of many prospective parents

There were some, Lord Samuel said, who suggested that the practice of contraception ought to be suppressed by law The Departmental Committee on Abortion said in its report

"We cannot accept the contention put forward in some quarters that the use of contraceptives to avoid pregnancy is fundamentally and in all circumstances wrong, and we doubt whether that view would be shared by more than a minority of persons in this country"

Even if suppression were attempted it was highly improbable that it would succeed Contraception was not the cause of the decline, it was the means by which it was effected The better course would be to remove the real cause—the desire for smaller families From the economic aspect a most effective means of doing this was the institution of family allowances as part of, or supplementary to, the wage system of the country In France such allowances had been adopted for many years, and now 7 million workers were covered by wage schemes involving allowances That meant the great *majority* of the workers of France No less than £20 million was distributed in France in 1937 in family allowances and the amount this year and last year would probably be far more There were also limited schemes in Belgium, Germany, New South Wales and New Zealand

It was necessary to make childbearing as safe, as painless and as inexpensive as possible for every mother in every class of society The question of extending national health insurance to the child dependents of contributors was also important, as was the campaign for better nutrition The removal of the marriage bar in certain occupations and extended income-tax reliefs for wives and children deserved consideration A definite population policy was needed, and attempts should be made to turn the current of public opinion in favour of marriage and parenthood and not against them The whole matter, especially the question of family allowances, should be investigated by a Royal Commission

Lord SNELL did not expect the fall in population to be calamitous He believed that the real problem of population was qualitative rather than quantitative, that it was darwinian rather than malthusian The late war robbed the country of something like a million potential fathers War itself was dysgenic in its effects, it took from the population the most

vital members and left behind those whose vitality was not so great. It was possible that this was only a temporary period, and that a new equilibrium of population would later be established.

A MEDICAL VIEW

Viscount DAWSON OF PENN agreed with Lord Snell that they must consider the quality of the people far more than their forefathers had done. The day had gone by when there were a large number of children born and Nature took off the weaklings. Today the nation was very properly trying to preserve its people, and something had to be done to take the place of Nature's methods But the graphs authoritatively issued showed that the fall in population was too great even if they did have regard to quality. This country had failed to reproduce itself since 1925. In 1880, the peak year, 100 women during their fertile period produced 150 girl babies. That was no doubt in keeping with the views on population of that particular period. No-one would wish that 100 women should produce 150 future mothers today. Now 100 women produced only 76 girl babies or future mothers. The curve had flattened out during the last two or three years, and Lord Dawson hoped that was a portent of better things. But however much they regarded quality they must have a big enough population to have an adequate turnover if they were going to bring the young people and the fit people to the top. The composition of the population was even more important than its numbers. In 1881 the proportion of people over sixty to those under twenty was as one to six. In 1931 the proportion was as one to three, and next year it would be as one to two. If the present trend went on, by 1960 there would be an equality, one and one, and that meant that there were not enough young lives coming in at the bottom to reinvigorate and replenish the nation. Already there was more accommodation in the schools than there were children to fill it A change might come, but the curves did not point that way at present.

It was sometimes said that the effect of civilised conditions was to reduce the amount of fecundity of both men and women, but there was no evidence of any mass tendency in that respect. The dominant immediate cause of the diminished size of families was contraception, which was extending in all classes and in all creeds. Contraception had come as the result of social changes; it was not due to a double dose of original sin, but to the evolution of life. It was only a specialised example of man's gradual control of natural forces One of the things that made contraception inevitable was the reduction in infant-mortality. The safety-valve of a high death-rate was taken away, too many children lived and therefore it was economically impossible to keep them. A way out had to be found somewhere. The woman of today was determined that her maternity should be a matter of choice not chance. She made her maternity a planned part, not the wasteful whole of her life through twenty years, as used to be the case. The chief reason why families were kept down was anxiety in some form or another. Before contraception was an established institution marriages in the early twenties were often impossible. Broadly speaking, he did not see any disadvantage in contraception provided parenthood was not postponed after the age of 25, but there was the risk that people would be apt to extend the childless period too far.

Lord Dawson suggested that the first remedy was further knowledge, which would allay fears about maternity, give instruction and bring home to people a sense of values A parenthood instruction service should be set up If they taught people how to rear babies in the child-welfare centres, was it not reasonable to go a step further back and teach them the wisdom of producing them?

The second remedy he suggested was social and economic Parents who were otherwise willing to bear their quota of children should not be financially penalised The state should help with some form of allowance which should relate to the children and not to the workers. It should be payable to the mother, if possible, and should relate to welfare and have little or no connexion with wages. If it was paid by tokens they should ensure that the money should go towards nutrition. The tokens should secure milk and such like things for the children. In regard to housing, they must provide for small communities in such a way that the children could have easy access to the air, and creches, nursery-schools, and other necessities should be provided If provision was made for continuous education after leaving school some of the difficulties they were discussing would be dissolved.

THE NEED FOR MORE DATA

Lord STAMP urged the necessity of a quinquennial census. He argued that if during the past century, with a much more leisurely time-limit of change than existed today, a ten-year census was right, surely something more frequent was necessary now. The fertility inquiry of the census of 1911 should, he said, be reintroduced. That should take precedence of other inquiries, for the information was urgently wanted by the bodies which were considering these problems. At the moment all their calculations had to be based on foreign comparisons. The question of the number of children born of each married woman, the number of children still living, and the duration of marriage were not merely academic questions to satisfy statisticians, mathematicians and population experts. They were the essential basic information, not merely for population problems but also for housing. A gap was left in our recent population statistics which the Government could fill. The occupation of the husband was done now by a schedule that was positively rudimentary and probably dangerous, or at any rate misleading. This ought to be made similar to the census of occupations. If they were to devise any rational policy they must know what the net reproduction-rate was for those in certain occupations or belonging to certain classes

Lord TEMPLEMORE, replying for the Government, said that this was eminently a subject where they must have reliable data, and complete data were not yet available. The most comprehensive material they possessed was at the disposal only of the Registrar-General, and his experience suggested that some of the published forecasts expected an earlier decline in population than the facts justified Some of the estimates made had already been falsified or discarded, and during the last six years the realised experience had pointed to a postponement of the date when a decline was possible. For the first time since 1873, the beginning of the decline, the birth-rate began to rise in 1934, and that tendency had continued unbroken for five years in succession. Whereas the percentage of increase of population fell till in 1933–34 it was 0 31 per cent, in 1934–35 it had risen to 0 43 per cent, in 1935–36 it was 0 45 per cent., and in 1936–37 0 44 per cent In 1937–38 there was a little decline to 0 42 per cent., but these figures emphasised the need for caution in forecasting future figures The marked check in the decline of the birth-rate during the past five years might be associated with the relative economic recovery of the country. Without suggesting that a decline in population was not a possibility after the next fifteen or twenty years, he thought that the matter was far more open than was generally believed A number of countries had adopted family-allowance systems, but in general it was not possible to detect any significant association between the allowances and the birth-rate. The only country with a record of a material increase in its birth-rate ensuing apparently from statutory political measures was Germany, where the rate rose from 14 7 per thousand in 1933 to 18 per thousand in 1934. For this change the introduction of a system of non-interest bearing marriage loans, 25 per cent. of which was cancelled on the birth of each child, was held to have been partly responsible. There was a considerable difference of opinion about the desirability

of adopting proposals of this nature The more sensational and pessimistic forecasts of population had been based on the assumption that the birth-rate would continue to decline below the 1933 minimum of 14 7 per thousand, whereas if the present level was maintained, even without further improvement, it was unlikely that the population would fall below the current total of 46 million for two or three decades They needed far more data before they could reach a basis for Government policy or action The Government had already taken steps to collect such data From the Population (Statistics) Act, 1938, which came into operation on July 1 last year, information would be obtained which would throw a valuable light on the varying incidence of fertility in different sections of the population, and a body of data would be built up from which details of the changes taking place from time to time would be immediately detected The collection of these data would, of course, take time Even if this did not directly reveal the basic causes of these changes, it would serve as an indispensable background of fact, both for the testing of variations in regard to the previous basic factors, and also for estimating and measuring the results of any concerted attempts to vary their natural course When the data became available they would be able to see whether the position was such as to demand action, and, if so, what action would be most likely to prove effective

Medicine Stamp Duties Retained

In the House of Commons on June 22 the clause in the Finance Bill repealing the medicine stamp duties was considered in Committee Mr GRAHAM WHITE said that it was not the duty of the Government to abandon revenue simply because they had reason to apprehend difficulties in administration If they threw over these duties and allowed the sale of remedies to go on without let or hindrance as to place, quantity or description that could only be an attack on the national health service of the country

Sir ARNOLD WILSON did not think there had been another occasion within living memory when more than 200 members of the House had begged the Chancellor of the Exchequer to continue a tax There was general agreement that the present duties were archaic and should go, and also that they should be replaced by something better If this clause were omitted from the bill the Government would be given the opportunity during the next twelve months to reconsider the whole subject The repeal of these duties would, unless others were substituted, facilitate the expansion of a trade which, to put it mildly, urgently needed control and restriction The chief medical officer of the Ministry of Health in his report for 1934 almost invited the taxation of medicines, even of the sort prescribed by doctors He said

> A considerable proportion of the total outlay on drugs prescribed by the medical profession, averaging 3s per head, could be limited without detriment, indeed with advantage and to the proper treatment of the people

Oliver Wendel Holmes went further when he told Harvard medical school

> If the whole materia medica could be sunk to the bottom of the sea, it would be all the better for mankind, and all the worse for the sea

Sir Arnold Wilson's nurse put it still more succinctly

> Remember, child, that doctors think
> More men have died from drugs than drink

No attempt, he said, had been made to devise an alternative scheme Was it to go on record that no scheme could be evolved by the Commissioners of Customs and Excise for a reasonable tax on medical preparations? He was assured that there had been no consultations officially or unofficially, with representative interests He agreed that pharmaceutical chemists had had a certain protection hitherto, but the 200 members of the House who were opposing repeal held that those chemists should have that protection They ought to be protected from competition by grocers, cheap-jack stores, and hawkers The repeal of the tax would discourage the publication of formulæ, a matter of real importance Most members had lost all hope that the Ministry of Health would promote a bill dealing with proprietary medicines At least ten attempts had been made by private members to get such a bill through Parliament, but they had all failed Now, in the 5s stamp booklets to be bought at post-offices, drugs were advertised which had been specifically banned by name as fraudulent by the whole press of Fleet Street The Minister of Health ought to bring in a bill to prevent his colleague from advertising medicaments which were notoriously dangerous

Dr HADEN GUEST said that the repeal of this tax amounted to an attack on the health of the people of this country It would, of course, be of tremendous advantage to certain large interests The work of the patent-medicine vendor was based on the exploitation of fear, and was buttressed by the prostitution of medical terminology in the service of boosting quack remedies If this proposal passed, the Chancellor of the Exchequer would be immortalised in the future as the "stop me and buy one" Chancellor of the patent medicine industry

Sir HENRY MORRIS-JONES said that not only the retail chemists, but all the drug trade, all the medical profession, and a large body of public opinion in the country were completely mystified as to why at a time when the state was in greater need of revenue than it had been in living memory, they should throw away a tax bringing in a million pounds a year, while at the same time jeopardising the public health of the country

Dr EDITH SUMMERSKILL said that if this clause was allowed to stand the Chancellor would be aiding and abetting a gigantic swindle throughout the country An opportunity would be given to every bogus patent medicine vendor to flood the market with any preparation he liked without obligation to put the formula on the box A few months ago there were certain preparations on the market containing iodine which were being used by young girls for slimming It was exceedingly dangerous for young girls to use iodine preparations There were two or three fatal accidents as a result of overdoses, and these preparations were withdrawn Now it was proposed to open the market again to those who put on to it these harmful drugs

Mr ALEXANDER urged that where the formula of secret remedies was not disclosed to an independent and qualified body, that particular commodity should be banned If they really wanted to control patent medicines in the interests of the health of the people, such commodities, whether dispensed by a pharmacist or not should be banned altogether

Sir JOHN SIMON, Chancellor of the Exchequer, said that it was not very likely at this time of day that he wished to lose revenue These medicine stamp duties were one of the curiosities of the statute book. They had been described by a learned judge as "a mass of confused and obsolete verbiage" They were 130 years old They were enacted at a time when ideas about medicines and cures were very different from today, and the attempt to retain them involved all sorts of ridiculous distinctions For example, the law provided that duty was to be paid if the remedy referred to an organ of the body, but there was to be no duty paid if the same remedy referred only to the organ of the body and did not mention the ailment If one offered "kidney pills" there was no duty, but if one called them "back ache kidney pills" a tax had to be paid It was true that the administration by the authorities of this tax was challenged, and it was a very serious thing for the Chancellor of the Exchequer to allow a challenge to go against a tax which his officers were collecting; all the more so when the advice he was given was that his position was exceedingly doubtful The truth was that it was impossible to apply the acts as they should be

applied. He could well understand that there were questions of public health and public control involved here; but he could not agree that medicines were a good subject out of which to raise taxation. The select committee in their report recommended that a duty should be imposed on a very wide range of medicines and remedies, practically all medicines and remedies except those made up from the prescription of a doctor. If that was the view of the committee as a whole it certainly did not agree with his view. He had done his best to see if he could find a tolerable modification, but he had failed. The select committee took the opinions of a large number of people, including witnesses speaking for the British Medical Association, who strongly took the view that the existing taxes were not justified, and asserted that if one wanted to try and discourage quack remedies the right way to do it was not by taxation But having taken evidence the select committee proposed a new scheme of duties Under their proposals there would have been no preference to chemists at all. A whole range of things would have been brought under the duty, in fact anything except a doctor's prescription. Was it really the general view of the committee that he should have adopted that alternative? This duty did not protect the public health at all. (An hon member. "Yes it does.") He was only expressing his humble views.

Dr GUEST: Against all the medical and pharmaceutical profession

Sir JOHN SIMON I do not think I can be accused of that, since I am relying on the evidence given by a spokesman of the British Medical Association, Dr. Bowman, who before the committee said he did not consider that the interests of health were to be served by putting taxes on things, but by regulations.

Dr. SUMMERSKILL. . When a doctor makes a statement of that sort it does not mean that he has circularised the profession and asked their views in any way He is not speaking for the whole profession by any means; they are his own views

In conclusion, Sir JOHN SIMON said that evidently the sense of the committee was that they would like, if it was at all possible, to get some new mode of treatment combined with the repeal of the duties He did not feel at all confident that that could be done, but he was perfectly willing to take the matter up with any other department concerned, and see whether it could. He was willing to maintain the present duties for another year. (Cheers) In the interval they must see whether it was possible to examine the position both as regarded the possibility of this or any other tax, and also as regarded the aspect of public health.

QUESTION TIME

JUNE 21–28

Medical Examinations of Militiamen

Mr LAWSON asked the Minister of Labour if he could give the latest figures with regard to the medical examination of militiamen.

Mr. ERNEST BROWN The number of men medically examined up to June 19 was 49,586 Of these 41,297 or 83 3 per cent. of the total were placed in grade I, and 4553 or 9·2 per cent in grade II, but of this number more than half were in that grade only on account of defects of vision or feet The total number of men passed fit for the two grades now being called up for training is, therefore, 45,850 or 92 5 per cent Of the remainder, 2443 men or 4 9 per cent of the total were placed in grade III which is the grade appropriate to men who would be fit for certain selected occupations in the forces but are not at present to be called up for the militia The number unfit for any form of military service and placed in grade IV was only 1293 or 2 6 per cent. of the total The following table gives corresponding figures for each of the administrative divisions of the Ministry

MILITARY TRAINING ACT, 1939 ANALYSIS OF RESULTS OF MEDICAL EXAMINATIONS DURING THE PERIOD JUNE 8 TO 19, 1939

The Question of Standard

Mr LAWSON asked whether the standard for these militiamen had been lowered as compared with the regular soldier —Mr. BROWN said that the medical examinations of the regular forces had in view the need of particular units, while the examination of militiamen was of a more general character

Mr LAWSON. Is the right hon. gentleman aware that the Army report on the conditions of health and examination shows no difference of that kind, and that we have always been led to believe that there was a general standard? Is he aware that his statement has led people in all parts of the country to believe that the standard has been lowered for militiamen and that his answer has given colour to that statement?—Mr. BROWN That is not so I am informed that the standards have been changed in some respects in regard to the regular army in recent years So far from the report showing what the hon member suggests, if he will refer to the annual reports for 1936 and 1937 he will find the details of these changes.

Mr. SORENSEN Can the right hon gentleman inform the House whether the present medical examination is more or less severe than the one carried out during the last war?—Mr BROWN · It is much more detailed Hon members who served last time will know that during the war the examination was conducted by one medical man as a rule In this case there are four medical men working under a chairman

Mr SORENSEN · Is it not true that the length of the examination is only four or five minutes, and in those

circumstances could there really have been a very thorough examination of the militiamen?—Mr BROWN, I suggest that I arrange for the hon member to attend at one of the medical boards and see for himself

Mr SORENSEN May I take it that at a very early date after the examinations have been completed we shall have these detailed records in order that we may have a very good insight into the medical condition of an important section of the community, and also in order that we may avoid the impression that prevails in some quarters that under any circumstances the men have got to be inside the armed forces?—Mr BROWN That impression is entirely false I should have thought that every member of the House, and everybody outside, would be proud of the fact that our social legislation within the last thirty years has given us these great results

Particular Defects

Mr JOHN MORGAN asked the Minister of Labour if he was aware that X. Y had been passed as fit for military service even though he wore a glass left eye, and would he state the regulations covering such a decision.—Mr ERNEST BROWN replied The instructions to the medical boards provide that persons with one eye only may be placed in grade II and marked "(a) vision," provided that that eye is free from disease and reaches a specified degree of visual acuity

In reply to a further question by Mr SORENSEN, Mr ERNEST BROWN said I regret that it is not practicable at the present stage to analyse the results of the medical examinations so as to furnish statistics of particular physical defects but I will consider what can be done when the examinations are complete Militiamen with only one eye may, in certain circumstances, be placed in grade II if the other eye is sound Men with defects of hearing may be placed in grades I–IV according to their condition The men examined are not tested for colour-blindness The examination includes a scrutiny of the teeth, and militiamen reporting for training will be fitted with artificial dentures, where this is considered essential, and without charge

Militiamen and Disability Pensions

Mr STEPHEN asked the Secretary of State for War if all militiamen who broke down in health during the period of service and were no longer fit for work would be allocated pension in view of the fact that they had been certified as fit men before being called upon to undertake such service—Sir V WARRENDER, financial secretary to the War Office, replied A militiaman will be eligible for a disability award if his disability is attributable to service It will be appreciated that, although a man may be passed fit on entering the service, he may subsequently acquire a disability, or a latent disability may manifest itself, which has no connexion with his military service

Mr STEPHEN asked the Minister to see that the examination was conducted so that latent disabilities would be discovered before the men passed into the army—Sir V WARRENDER I think that is beyond the wit of the medical profession

Mr STEPHEN If it is beyond the wit of medical men, will the Minister see that information is given in every case, when the medical man certifies that the man is fit for service, if he develops disabilities afterwards?—Sir V WARRENDER We endeavour to deal with cases in as kindly a fashion as we can, trying to avoid hardship, but it would be impossible to accept liability for all accidents which might happen to a man during his service

Mr SILVERMAN asked whether if the medical examination could not possibly disclose some latent defect it was possible for medical evidence at a later date, when the defect developed, to be sure that it was not due to military service—Sir V WARRENDER said that there had to be some evidence that the man underwent some exposure or hardship during his military service to which his disability could be traced

Mr SANDYS Is it not the fact that six months' training can improve a man's health?

University Students and Military Training

Sir JOHN MELLOR asked the Minister of Labour whether, in view of his consultations with representatives of the universities and schools, he was now able to make a further statement with regard to the antedating of militia training in the case of boys who intended to proceed to the universities after October, 1939—Mr ERNEST BROWN replied Yes, Sir At a meeting held under the auspices of my department on Monday last between representatives of the committee of vice chancellors and headmasters, together with representatives of the departments concerned it was agreed to recommend that boys intending to proceed to the universities were given the double option of postponing or anticipating their liability to undergo military training I intend to put this agreed conclusion into operation, subject to reviewing the position in twelve months' time in the light of experience, when I propose again to seek the advice and assistance of the representatives of the universities and the schools It was further agreed at the conference that anticipation of the liability to undergo training in respect of such boys should not be granted to those under the age of 18 years on Jan 1 of the year in which they wish to take their training With regard to this recommendation, I cannot do more at present than say that it will be borne in mind when applications for anticipation are considered

Mr MANDER Was this agreement unanimous?—Mr BROWN Yes, Sir

R A F Medical Tests

Mr GORDON MACDONALD asked the Secretary of State for Air how many applications had been made to join the Royal Air Force during the last 12 months, the number accepted, and how many failed to satisfy the medical tests, and the principal causes of such failure—Sir KINGSLEY WOOD replied The total number of applications to join the regular Royal Air Force during the 12 months ended June 17 was 91,447 41,325 acceptances resulted from these applications, and there were 18,105 rejections on medical grounds The principal reasons for such rejections were visual defects and physique below the required standard

Mr MACDONALD Can the right hon gentleman say whether his department take any action in regard to those rejected on such grounds and try to get the disability removed?—Sir KINGSLEY WOOD I will inquire

Hospital Staffs and A.R P Badges

Mr HUBERT BEAUMONT asked the Lord Privy Seal why officers and staffs of county hospitals and institutions who had taken the essential courses of training and passed examinations in connexion with air raid precautions were not being issued with air raid precautions badges—Sir JOHN ANDERSON replied The air raid precautions badge is intended as a recognition of the obligations undertaken by persons who volunteer for local authorities' and other air raid precautions services, and persons who take special courses of training in order to enable them to carry out their normal duties under war time conditions are not merely by reason of their having undergone such training eligible for the badge I understand, however, that the Minister of Health has under consideration the question of providing some other special form of recognition for the staffs of hospitals and institutions in such circumstances as are mentioned in the question

Civil Defence and Evacuation of Young Children

Mr DAY asked the Minister of Health what information he had received as to the success or failure of the scheme for registration for the evacuation of children under five years of age, and what steps he proposed to take to ensure the safe evacuation of the younger child population from districts outside the London area—Mr ELLIOT replied I have received returns from a number of evacuation areas which show that the initial response from mothers of children under five has so far, in many cases been encouraging The registers are in general still open In London the returns have been lower than in some other towns, and I would appeal to mothers with young children

to register. The Government evacuation scheme already applies to eleven areas immediately adjacent to the administrative county and to twenty-two provincial areas. As indicated in a reply which I gave on May 18 I am reviewing the possibility of extending the scheme to certain further areas

Army Rejections on Medical Grounds

Mr. WILLIAM JOSEPH STEWART asked the Secretary of State for War the number of men who enlisted in the Regular Army during 1938 and 1939 and the number of applicants who were rejected on medical grounds—Sir V. WARRENDER replied: The numbers of recruits finally approved for the Regular Army during the calendar year 1938, and during the period Jan 1 to May 31, 1939, were 38,827 and 20,197 respectively The numbers of applicants for enlistment into the Regular Army during the periods in question who were rejected at medical examination were 7299 and 3278 respectively.

Mr. GORDON MACDONALD asked for the number of persons offering themselves for enlistment who, on being found below standard, had been sent to one of the recruits physical development depots; and also whether the results had been satisfactory.—Mr HORE-BELISHA replied: The number sent to the depots is 2775 Of these, 2044 have been posted to units as fit and only 196 failed to reach the standard after training.

Silicosis Scheme

Mr JAMES GRIFFITHS asked the Home Secretary when the order extending the period of certification under the Various Industries (Silicosis) Schemes would be issued; and if he could state the provisions contained in the order, and whether it would be made retrospective—Mr. PEAKE, under-secretary, Home Office, replied: The amending scheme was made on June 12 and I understand that copies are now available. The scheme extends the limit in the proviso to paragraph 4 of the principal scheme from three years to five My right hon. friend was advised that he had no power to make it retrospective. He has, however, suggested, through the Mining Association, that the colliery owners might undertake to deal with claims where the workman has been employed in the mines within the three years preceding the date of the amending scheme, as if the limit in their case were five years and not three I understand that this suggestion is under consideration.

Young Persons in Factories

Mr. PARKER asked the Home Secretary what representations he had received from manufacturers asking him to suspend the coming into force of section 71 of the 1937 Factory Act on July 1, 1939, and to suspend section 73; and what answer he had given—Sir SAMUEL HOARE replied: I have no power to suspend either of these sections but section 71 contains a provision that the coming into force of the section is postponed as respects any particular industry where a public inquiry has been ordered but no final decision has been reached on the question of fixing for that industry a higher figure than 44 as the maximum number of working hours in a week for young persons under 16 A considerable number of applications for more hours than 44 has been received. Many have been refused or withdrawn; in the case of some industries inquiries have been or are to be held; and in the case of some others the question of directing an inquiry is now under consideration Under section 73 there is power to extend within certain limits the overtime permissible Regulations for that purpose have been made for various classes of factory, and applications from some other industries for such regulations are still under consideration

Cheap Milk for Mothers

Mr TOM SMITH asked the Minister of Agriculture how much of the exchequer subsidy voted under the Milk (Extension and Amendment) Act, 1938, was being used to help maternity and child-welfare authorities to start cheap milk schemes, and the price charged to the local authorities for the milk; how many authorities had inaugurated such schemes and their names; how many expectant and nursing mothers were receiving milk free and for payment, and the price in the latter case; and how much milk was normally given daily in each case and for what period.—Sir R DORMAN-SMITH replied While I am hopeful that it will be possible to introduce in the near future a scheme for the supply of milk at reduced prices to English local authorities in connexion with their maternity and child-welfare arrangements, negotiations to that end have not yet been completed No sums have, therefore, as yet been paid under the Milk (Extension and Amendment) Act, 1938, in respect of milk supplied under such a scheme in England A scheme has, however, been introduced for the area of the Scottish Milk Marketing Board

Contagious Abortion in Cattle

Mr W. ROBERTS asked the Minister of Agriculture whether he proposed that free testing of cattle for contagious abortion should be now included in the provisions of the Attested Herd Scheme—Sir R DORMAN SMITH replied: Under the powers conferred by part IV of the Agriculture Act, 1937, a scheme is being framed whereby owners of attested herds will be assisted, by the provision of free veterinary advice and free blood-testing, to protect such herds as are already free from abortus infection and to eliminate disease from abortus-infected herds I hope to be in a position to introduce the scheme within the next few months

Smoke Abatement

Mr. DAVID ADAMS asked the Minister of Health whether he was aware that a pottery factory in Staffordshire had been converted to electric power, whereby smoke had been entirely eliminated; and what steps he was taking to induce other industrialists in the potteries and elsewhere to follow this example in the interests of cleanliness and smoke abatement—Mr. ELLIOT replied: I am aware that electricity has been used for some time with great success in certain trades in the potteries My chief alkali inspector in recent annual reports has urged the extension of the practice and has stressed the advantages of electricity and gas where available on economic terms particularly in types of industry that are normally productive of heavy smoke. I have no doubt that smoke prevention authorities and industrial organisations in this and other industrial areas of the country are aware of the possibilities of the cleaner methods, the use of which I greatly welcome

---

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 17, 1939

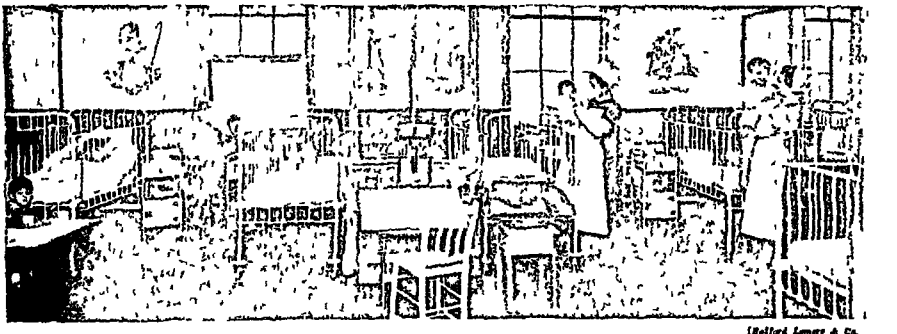
Notifications.—The following cases of infectious disease were notified during the week: Smallpox, 0; scarlet fever, 1549; diphtheria, 755; enteric fever, 21 (28 "expected"); pneumonia (primary or influenzal), 635; puerperal pyrexia, 185; cerebro-spinal fever, 21; acute poliomyelitis, 15; acute polio-encephalitis, 1, encephalitis lethargica, 4, dysentery, 21; ophthalmia neonatorum, 95. No case of cholera, plague or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on June 23 was 2829, which included: Scarlet fever, 659, diphtheria, 488 (carriers, 24), measles, 5, whooping-cough, 845, puerperal fever, 19 mothers (plus 9 babies), encephalitis lethargica, 304, poliomyelitis, 3. At St Margaret's Hospital there were 22 babies (plus 1 mothers) with ophthalmia neonatorum

Deaths.—In 126 great towns, including London, there was no death from smallpox or scarlet fever, 1 (0) from enteric fever, 2 (0) from measles, 14 (3) from whooping-cough, 17 (2) from diphtheria, 30 (9) from diarrhœa and enteritis under two years, and 14 (1) from influenza. The figures in parentheses are those for London itself.

York reported the only death from typhoid Birmingham had 2 deaths from whooping-cough Fatal cases of diphtheria were scattered singly over 15 great towns, Liverpool reporting 3. Birmingham had 3 fatal cases of diarrhœa

The number of stillbirths notified during the week was 218 (corresponding to a rate of 32 per 1000 total births), including 26 in London.

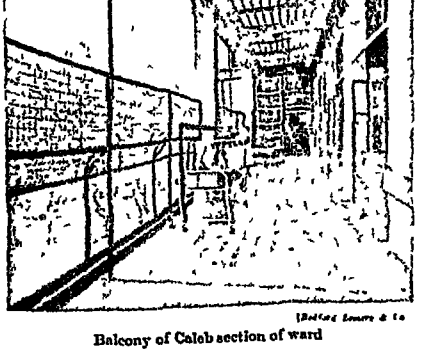


[Bedford Lemere & Co.

Part of Diplock section of ward

NEW CHILDREN'S WARD AT GUY'S

THE allocation of £21,000 from the estate of the late Caleb Diplock has made possible the construction of a children's ward at Guy's commemorating his name The new ward is now completed and is one of which any hospital in the world might well be proud, and it is particularly appropriate that Dr H C Cameron should have been invited to remain on the active staff for two years after the normal age of retirement in order to see fittingly housed the department he has built up The ward occupies the site of the old Bright ward in Hunt's House, and has been reconstructed to provide 47 cots or beds, of which 18 are surgical, 28 medical, and 1 is for the infant of a nursing mother, 10 of the cots are available for paying patients, in order to help meet the increased running expenses of the ward The ward consists of two main sections (surgical and medical) separated by a main hall A 10 ft covered balcony, with a glassed-in playroom for older children at one end, runs the length of the sections facing on to the park, and the windows on this side open to the floor to allow each bed to be wheeled straight out of doors From the central hall, which is available for demonstrations, sorting linen and so on, open the two sisters' rooms, the kitchen, milk laboratory, pantry, and autoclave room, and the children's operating theatre and anæsthetic room



[Bedford Lemere & Co.

Balcony of Caleb section of ward

Both the medical and surgical sections are subdivided into a number of wardlets by glass partitions 6 ft 9 in high, the larger wardlets contain 6 cots, and the smaller 4, 3 or 2 cots An isolation cubicle glassed to the ceiling and having a separate bath and sluice is available for infectious cases A particularly valuable feature is a small flat for a nursing mother to live in when her baby has to be admitted either for operation or for medical or feeding difficulties There is a consulting room for history taking and the keeping of records

Each wardlet is provided with a large hand basin, suitably placed and shaped for use as an infant's bath, thus obviating any need for removing infants elsewhere for their toilet Labour saving devices include a bottle-washing machine, fixed bedpan sluices and steriliser, an autoclave for infants' feedings, and panel heating in the ceiling with thermostatic control for maintaining the temperature of the ward at 65° F Perhaps the most obvious attraction of the ward is the light green and primrose tiling of the walls, into which are set coloured nursery rhyme designs Each wardlet is fitted with concealed floor lighting and dimming devices on the overhead centre fittings, an advantage in dealing with sleeping children at night

The ward will be a blessing to the children of "the Borough," and will give lasting satisfaction to the many Guy's men who have long felt its need

---

YORKSHIRE TUBERCULOSIS SOCIETY.—This society, which was resuscitated two years ago, under the presidency of Dr N Tattersall, has just completed the session with an annual meeting held at Killingbeck Sanatorium by invitation of Dr W Santon Gilmour At the four meetings held during the winter: (1) Dr Peter Edwards read a paper on methods of obtaining complete collapse of the lung and demonstrated the results of adhesion-cutting (2) Dr John T Ingram proved that, in spite of the chronicity of the lesion, there is great hope for lupus if patient and persistent treatment is carried out (3) In a paper on the pros and cons of arthrodesis, Dr H L Crockatt professed a conservative attitude although agreeing that cases of non bony union should be assisted by open operation (4) Short papers on the diagnosis of abdominal tuberculosis in children (Dr Margaret Sharp) and cases of transient positive sputum (Dr S P Wilson) provoked lively discussion

UNITED STATES OF AMERICA

(FROM OUR OWN CORRESPONDENTS)

A MUSEUM OF HEALTH

AT a ceremony in the Hall of Man at the World's Fair on June 17 a new American museum of health was dedicated before an audience of several hundred doctors and public-health officials. Dr. Livingston Farrand, president-emeritus of Cornell University, took charge of the proceedings and introduced a series of distinguished speakers, all of whom emphasised the importance of health education in forwarding the cause of public health. Prof Abel Wolman, the president of the American Public Health Association, did so by drawing attention to the backwardness of the United States in applying the discoveries of science He pointed out that although it is an accepted axiom that the individual is the first line of defence against disease, America has the distinction of leading the civilised countries of the world in smallpox, a disease from which the individual can be completely protected. The organisms of tuberculosis and syphilis were discovered many years ago, yet, though progress has been made in controlling tuberculosis, the progress of our campaign against syphilis has been blocked not by scientific ignorance but by social prejudice The American people are not so healthy as they have a right to be, and in fact public health has never been the first consideration of the state except in times of disaster. Other speakers dwelt on the possibilities of the exhibit surrounding them in the Hall of Man Dr. John L Rice estimated that four million out of the seven and a half million persons of New York city would visit the fair, and asked his audience what it would mean to the city if each of them should carry even one idea from this exhibit into their daily life But the exhibit of the fair is to be only the beginning A permanent museum housed in the city of New York with its continuous exposure to the population will result in a still greater cumulative effect Mayor LaGuardia, twitting Dr. Wolman on his pessimism, prophesied that if he were allowed to continue his programme for sanitary housing, nurseries for poor children, and nourishment for the unemployed, tuberculosis would be eliminated in New York city in the next 25 years. But if this end is to be achieved, the responsibility of the government for public health must be recognised. He announced his intention of building a new court-house for the Appellate Division and said that the present fine building at Madison Avenue and Twenty-fifth Street would then be converted into a home for the Museum of Health.

NATIONAL HEALTH BILL

Last month expert medical evidence was offered before a subcommittee of the senate committee which is considering the Wagner National Health Bill Dr Arthur W. Booth, who represented the American Medical Association, expressed the opinion that the enactment of this measure "would prove a costly mistake, jeopardising the welfare of the people and seriously compromising the future development of the science and art of medicine in the United States" He said that the projects embodied in the bill had been devised by federal officials and that they do not represent the wishes of the people The house of delegates in September, 1938, recommended the establishment of a federal department of health with a secretary as its head The bill provides no such centralisation of authority. The house of delegates also required that expansion of health services should not include provision of medical care, which can be successfully provided by the general practitioner The bill does not, in Dr Booth's opinion, provide any safeguards for the existence of the private practitioner. The bill does not limit expansion of hospital facilities to situations in which need exists nor does it limit the provision of medical care to the poor Dr. Booth felt that the federal bureaus were given too much power over the states, but when Senator LaFollette asked him to indicate the specific powers to which he objected he replied that he had not read the entire bill.

Dr. Richard M. Smith, chairman of the Committee of Physicians for the Improvement of Medical Care, urged the need for coördination of all kinds of medical care under a single administrative authority, aided by a single advisory council. In the organisation of medical care, he said, it is important that public health services should be under the control of trained full-time salaried experts The needy should become eligible for medical care without delay or indignity. Provision should be made for the support of education and investigation.

Prof John P. Peters, secretary of the Committee of Physicians, said that the committee is in general sympathy with the bill. They are interested in strengthening the machinery which can guarantee a high quality of medical care, for this will also protect the public against excessive expenditure. In his opinion the bill is intelligently conceived to meet a demonstrated need The increased costs of medicine arise not from the rapaciousness of physicians but from the nature of modern medicine Government aid is made imperative The bill wisely leaves development and administration of programmes to the several states; it is equally wise in providing that federal authorities shall prescribe standards of qualifications for the receipt of grants in aid.

AUSTRALASIA

(FROM OUR OWN CORRESPONDENT)

NATIONAL HEALTH INSURANCE

THE editor of *Medical Topics* has admirably expressed the situation of national health insurance in Australia "National insurance has Cheyne Stokes breathing Signs of approaching death are evident in the act, but no one in the government has sufficient courage to put the poor thing out of its misery"

For some time it has been evident that the Australian government wants to abandon the National Health and Pensions Insurance Act placed on the statute book last year; but, national insurance being one of the main points upon which the last election was won, such action would require considerable courage—in spite of the almost national feeling against the act—which the government, in an already precarious position, has felt unprepared to show In March it decided to substitute a medical service plan repealing the pensions provisions and leaving only a system of health insurance and family medical benefit It was intended to continue the approved society system and the cash health benefits on substantially the same scale as originally provided, but the whole question of medical benefit was to be discussed first with representatives of medical benefit organisations and of the medical profession and later with the consultative council of approved societies

This substitution of a health service for the original scheme was introduced only at the expense of the

resignation of the attorney general Mr R G Menzies Now, after the sudden death of Mr J A Lyons, Mr Menzies has been recalled as prime minister to lead a new cabinet It is doubtful, however, whether this shift of power will make any significant change in the attitude towards insurance Having so strenuously opposed its abandonment several months ago, Mr Menzies no doubt feels it incumbent upon him now to make a further attempt to save the scheme He has promised to ask parliament to set up a committee of members with whom will be associated representatives of the medical profession and approved societies and the National Insurance Commission, "to see whether a practical scheme, in which all parties will cheerfully and patriotically coöperate, can be evolved"

Appearances, however, are all against the continuance of national insurance It has been officially announced that it is impossible to bring the health scheme into operation on Sept 4—the date to which it was last postponed, the National Insurance Commission's activities have been largely suspended, the approved societies have been instructed not to proceed with any further plans, and the royal commission on doctors' remuneration has not been reconstituted since the death of its chairman, has not made a report, and so far has been obviously unable to reach a basis which would ensure the coöperation of the medical profession

THE NEW ZEALAND POSITION

In New Zealand the question of insurance has taken on a rather different, though equally difficult, complexion The Social Security Act, 1938, officially began to operate on April 1, but a deadlock persists between the government and the medical profession, and of a possible 750 only 22 practitioners have accepted contracts under the act

The act entitles every man, woman, and child ordinarily resident in New Zealand to certain benefits, including pensions, unemployment insurance, medical, hospital, and maternity benefits, and the supply of medicine and appliances Supplementary benefits will be introduced later, such as specialist and consultant, radiological and laboratory, home nursing and domestic, and optical and dental services The act ensures adequate services in sparsely populated or isolated areas Provision has been made for the immediate institution of a health education campaign, and the scope of medical research is to be extended The government has given its assurance that the professional standard of medical men and others giving service has been safeguarded, that care has been taken not to disturb the personal relationship between doctor and patient, that all citizens have the right to make a free choice of doctor, and that every doctor will have an opportunity of participating in the service

However, in spite of these assurances, and since the date on which the act was to come into force, the New Zealand branch of the British Medical Association has unanimously decided that the government's scheme is inadequate and unacceptable, and that its members are unable to coöperate in its administration, being completely opposed to the present scheme, which offers all the people part or limited medical service, as against the association's view that a free complete service should be provided for those unable to pay for it

Commenting on this attitude, the prime minister has stated that the government, in introducing this legislation, was complying with the wishes of the people—at last year's election the government was returned with an overwhelming majority almost entirely on the question of social security—and that it would therefore make the best arrangements possible to give effect to those wishes If the profession, under the leadership of the B M A., was determined to persist in its policy of opposition, the government would have no option but to alter the whole basis of service and to proceed reluctantly with the establishment of a state medical service to administer the benefits of the Social Security Act The position is serious for the profession Ultimately, however, it must be the people who determine what form of medical service they shall receive In New Zealand it appears they are strongly in favour of a universal insurance scheme, and it behoves the profession to make the best possible arrangements in the circumstances

LETTERS TO THE EDITOR

PROBLEMS OF DECLINING FERTILITY

SIR,—We should be grateful if we might be allowed to draw the attention of your readers to an inquiry into the causes of infertility which is being promoted by the committee to which we belong These causes have been much discussed of late in Parliament and elsewhere It will be recalled that the main object of the Population Statistics Act, which came into effect on July 1, 1938, was to throw further light upon this subject

But there are strict limits to what we may learn from vital statistics They can tell us nothing, for instance, about how many marriages are involuntarily sterile or sterile by design, nor of the extent to which abortion and contraception are practised, nor about the numerous motives which restrict parenthood in different regional and occupational groups These problems can only be clarified by direct inquiry

A questionnaire has been prepared by our committee If filled in on a large enough scale it will yield information which is otherwise unobtainable It has been designed for the use of doctors, midwives, nurses and other competent investigators and has been drawn up on the same general lines as were followed by Prof Raymond Pearl in his comprehensive American inquiry The committee is anxious to obtain records of the attitudes and experiences of as large a sample as possible of married women in this country irrespective of age and parity

We should therefore be very grateful if those of your readers who are interested in the problems of *declining fertility*, or in problems allied thereto, would assist the committee by sending for copies of its questionnaire and by filling them in when appropriate occasions present themselves An honorarium of 1s per filled in questionnaire is offered A small manual has been prepared which provides guidance in the use of the questionnaire Will those of your readers who are interested kindly communicate with the secretary of the Population Investigation Committee, 69, Eccleston Square, London, S W 1

We are, Sir, yours faithfully,

CARLEY HOLLAND,
HENRY BRACKENBURY,
HORDER,
C P. BLACKER

June 25

BLOOD FOR THE SERVICES

SIR,—All those engaged in the present emergency in the organisation of blood-transfusion services in this country would, I think, welcome further information as to the proposed Army blood-transfusion service referred to in your annotation of June 17 For this service it is apparently proposed to draw upon the civilian population for blood for use by the Army. Yet the need of the civil population for blood for purposes of transfusion may, on occasion at any rate, be at least as great as that of the Army.

The need for a nation-wide blood-transfusion service capable of expansion on the outbreak of hostilities is obvious; local effort mainly centred around the voluntary hospitals and without support from any central authority is in many areas doing its best to meet this need If public funds and the blood of the general population are to be made available for maintaining a blood-transfusion service it seems eminently desirable that it should be for the benefit of all classes of the population, civil and combatant alike.

I am, Sir, yours faithfully,

S. C. DYKE.

Pathological Laboratories, Royal Hospital, Wolverhampton, June 24

DÉBRIDEMENT AND DÉBRIS

SIR,—My attention has been drawn to the fact that the use of the word *débridement*, in my article last week on the closed treatment of war fractures, is likely to lead to some confusion. The word is the French technical term for incision with opening up of the fascial planes and has no relation to the word *débris*. Where removal of dead or dying tissue was intended I added the words "and excision"

I am, Sir, yours faithfully,

Eton Avenue, N W 3, June 26. J. TRUETA.

THE PROBLEM OF MEDICAL LITERATURE

SIR,—There is much truth in what Professor McDowall writes The present state of medical literature is disheartening, but I think it is too pessimistic to assert that there is no prospect of improvement. There is no doubt about the need for greater coördination between medical libraries. Actually librarians do consult and help one another to a considerable extent in an informal manner, and this coöperation is likely to increase Though various journals may be "scattered all over the libraries of Britain" it is easy to find out where each journal is situated, and at slight expense obtain a photostatic copy of any particular article; it is likely that in the near future microphotography will greatly increase the facilities for such dissemination of knowledge.

It is clearly impossible for every library to take in every medical journal, and if the necessary knowledge is to be made available there appear to be two remedies at our disposal One is that suggested by Professor McDowall—the publication of a medical abstracting journal, supplemented perhaps by occasional systematic reviews; this would be a great help but would not absolve the student from referring to original articles. The second and in my opinion a complementary step would be the maintenance of at least one large library where all the rarer and more expensive books and journals could be taken; this library ought to work in close coöperation with all other medical libraries, and would need to have a special staff for the work of preparing references and translations, and be equipped with the latest apparatus for photostatic and micro photographic reproduction.

This is the ideal which the library of the Royal Society of Medicine, within the limits imposed upon it, has tried to approach; but it is clear that complete success could not be achieved by any library without endowment.

I am, Sir, yours faithfully,

Harley Street, W 1, June 26 V. ZACHARY COPE.

SIR,—Anyone with practical experience of the matter can hardly do other than agree with Professor McDowall and Mr Lloyd No real solution to the problem will be found however until the enormous output of periodical medical literature is reduced by some such drastic measures as those proposed in your recent leading article on micro-films (April 1, p 765) With regard to a medical abstract journal it might be instructive to know the reasons for the early decease of *Medical Science: Abstracts and Reviews*, which was published by the Medical Research Council from 1919 to 1925

That medical librarians themselves are becoming alive to the need for closer coöperation is shown by the existence of two recently initiated schemes The first is an ambitious one organised by the university and research section of the Library Association. A list of all known medical periodicals, of which there are probably about 7000, is being compiled on specially printed cards on which a place is provided for recording the holdings of all scientific libraries in Great Britain and Ireland that possess medical periodicals This is a large task and may, quite probably, take years to complete The next step will be to persuade the library committees of the various institutions to cancel redundant subscriptions and, with the money thus saved, to buy other periodicals not at present available

The second scheme is limited to London and for the present is confined to the four medical libraries of the Royal College of Surgeons, University College, the London School of Hygiene and Tropical Medicine, and the Medical Research Council A union list of current periodicals has already been compiled and the four librarians have agreed, in cases where there is unnecessary duplication, which subscriptions they will recommend to their committees for cancellation

The success of all such schemes depends upon the willingness of library committees or other responsible authorities to allow inter-library loans and to sacrifice certain subscriptions. Unless libraries that possess a certain journal are willing to lend it to those that do not, it is obvious that these will not cancel their subscriptions, and unless these other libraries are willing to cancel their subscriptions to redundant journals, there will be no money available for new subscriptions. I should like therefore, through your columns, to appeal to any readers, who may find themselves in a position to exercise authority in such matters, to take the long view and give favourable consideration to any proposals for coöperation on the lines suggested above

I am, Sir, yours faithfully,

CYRIL C. BARNARD,
Librarian, London School of Hygiene and Tropical Medicine

Keppel Street, W C 1, June 26

LAY PSYCHOTHERAPISTS

SIR,—My committee have instructed me to ask the hospitality of your columns for the purpose of clearing up a serious misunderstanding which seems to exist among medical men about the aims and objects of the Guild of Pastoral Psychology

The guild desires to equip ministers of religion with sound psychological training so that they may better perform their pastoral duties It is not attempting to create a class of non-medical persons who would conceive themselves qualified to practise quasi-medical psychotherapy It envisages as its typical "fellow" a man who holds a cure of souls and who carries out the duties thereof more efficiently by reason of a training in psychology The guild considers that any minister who wishes to practise professionally as a psychotherapist should conform to the standards to be laid down by the British Medical Association and does not itself at present offer a training to such persons

Quite clearly, no medical man would wish to claim a monopoly over the whole field of psychology There is educational psychology, there is commercial psychology, there is industrial psychology—and there is also pastoral psychology The guild exists to define the limits of pastoral psychology, and the medical members of its committee are there to help it to ensure that pastors do not unwittingly infringe on the province of medical psychology

I am, Sir, yours faithfully,

BERNARD C EVANS,
Secretary

Broadbent Street, W.1, June 23

The senate of the University of Glasgow announces that the Struthers gold medal and prize has been awarded to George M Wyburn, D Sc, M B, F R F P S G, F R S E for an important series of embryological studies embodied in papers published in the *Journal of Anatomy* in January, 1937, April, 1938, and January, 1939 The Harry Stewart Hutchison prize has been awarded to James Holmes Hutchison for his dissertation entitled the iron-deficiency anæmia of childhood

Short Service Appointments in the Navy

The Admiralty announces that the following have received appointment as surgeon lieutenant, R N, for short service P W Edmondson M R C S, L A Penn, M R C S G N Reed, M B, J K Salmon, M R C S, and F B B Weston, M R C S

Extension of Harrogate Baths

Harrogate's new £100,000 spa extension scheme will be opened by the Lord Mayor of London on Monday, July 10 The new scheme provides for an entirely new building in which exclusively Harrogate mineral water treatments will be administered The equipment of the building and the treatment apparatus are said to be the last word in spa technique The capacity of the new building will be a thousand treatments a day In addition a new lounge hall has been constructed for the recreation of patients undergoing the cure Between the new building and the lounge hall is a fountain court surrounded by a covered colonnade, heated, and enclosed in glass shutters in winter, where patients may take gentle walking exercise while drinking the spa waters, and between the periods of treatment

A Postgraduate Class in Dublin

Our Irish correspondent writes A postgraduate class on for Ireland at least novel lines is just concluding a fortnight's work in Dublin It was novel in that it was organised as a co-operative undertaking by the entire ten general clinical hospitals of Dublin, each hospital acting in turn as host for one day It differed also from previous postgraduate courses in Dublin in that the tuition was entirely clinical, the medical schools as distinct from the hospitals taking no part in the course The experiment has proved a success as far more graduates entered for the course than had been expected—over 70 in all This degree of popularity was in fact embarrassing as the numbers were too large to render clinical demonstration easy It became clear that if the class is to be repeated in future years it must be divided into manageable groups The members of the class and their teachers dined together in the Royal College of Surgeons last Saturday evening under the chairmanship of Mr William Doolin, president of the College There were no formal speeches, but the members of the class, on the invitation of the chairman, offered criticisms and suggestions on its future management An interesting and instructive discussion followed which should help the development of postgraduate teaching in Dublin

Guy's Hospital

Applications are invited for the Astley Cooper studentship which is tenable at the hospital Particulars will be found in our advertisement columns

Mental Hospitals Association

The twenty-first annual meeting will be opened by the Lord Mayor of London in the council chamber of the Guildhall at 11 A.M. on Thursday, July 6 A discussion on the Matrimonial Causes Act, 1937, in relation to mental hospital practice will be opened by Dr. T C Graves, chief medical officer to the Birmingham mental hospitals committee

Appointments for Patients at St. Thomas's

St Thomas's Hospital has introduced a system by which outpatients are seen by appointment. So far only old cases have been catered for but the results have been so encouraging that the system is likely to be extended to new cases as well The report of the almoners' department foresees the time when "the mere idea that patients, except in an emergency, should come up to a hospital without an appointment will be regarded as fantastic"

Royal Medico-Psychological Association

The annual meeting of this association will be held at Brighton, on July 12, 13, and 14, when the new president, Dr. Helen Boyle, will give an address entitled Watchman What of the Night? and the principal subjects for discussion will be early treatment for mental and nervous disorders, and epilepsy from many aspects Tickets for the annual dinner may be obtained from the secretary, 11, Chandos Street, W 1.

Order of St. John of Jerusalem

The following appointments to and promotions in the Venerable Order of the Hospital of St John of Jerusalem have been sanctioned by the King —

As Knight—Urban Marks, M.R.C.S.

As Commander—Lieut.-Colonel Frank Romer, M.R.C.S., Sir Henry Gauvain, M.D., Francis Carr Bottomley, O.B.E., M.D.

As Officer—Henry George Ramsbottom, L.R.C.P.E., Norman Harold Kettlewell, L.M.S.S.A., L.D.S., Ernest Joseph Burnett, M.B.E., M.R.C.P., David Henry Griffiths, M.R.C.S., Gwilym Llewelyn Pierce, L.R.C.P.E., Robert James Clarke, M.B., Lieut.-Colonel Edward Slade Goss, M.C., M.R.C.S., I.M.S., Francis Joseph Bach, M.D., John Craven Glen, L.R.C.P.E., Major Eben Stuart Burt Hamilton, M.C., M.B., Eric Hoerman, M.B., Andrew Croll, M.D., F.R.C.S.E., Edwin Francis White, F.R.C.S., Major Colin Wilson, M.B., R.A.M.C., Charles Paul Gaboury, M.D., Clarence John Archibald McKillop, M.D., Major Wilmot Edward Lenox Sparks, M.D., Lieut.-Colonel Ronald Herbert Candy, C.I.E., M.B., I.M.S., Lieut.-Colonel Norman Briggs, M.R.C.S., I.M.S., Mrs Jane Pasley Hay Graham Brown, M.B.

Exhibits at the National Physical Laboratory

At the annual inspection of the laboratory on Tuesday last the special exhibits included photomicrographs and radiograms illustrating the structure of teeth It has been found that there is a gradual decrease in the degree of calcification from the outer to the inner surface of the enamel The inorganic constituent of the enamel has recently been proved to consist mainly of hydroxy-apatite, the crystals of which have an average dimension of 10–8 cm and are associated into prisms containing perhaps half a million crystallites The crystalline orientation deduced from radiographic appearances has been confirmed by the polarising microscope, which shows that within each prism, which extends from the dentine to the outer surface, there are in general two groups of crystallites, the one inclined at about 5° to the prism axis and the other at about 40° The primary objects of this investigation, undertaken for the Medical Research Council, are to determine the structures of the enamel and of the underlying dentine and to observe how these structures vary with different types of teeth Other exhibits of medical interest included apparatus designed for testing the accuracy of the colour of standardised tubes used in haemoglobinometry and apparatus for testing the accuracy of glass butyrometers used in determining the percentage of fat in milk.

Medical Diary

July 3 to July 8

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole Street, W 1

TUESDAY—5 P.M., annual meeting

THURSDAY

Surgery—8.30 P.M., Dr D W G Murray (Toronto): Heparin in Thrombosis and Embolism, Venous Grafts in Blood-vessel Surgery Film. the formation of a thrombus

EDINBURGH MEDICO-CHIRURGICAL SOCIETY

WEDNESDAY—8.30 P.M. (at the hall of the British Medical Association, 7, Drumsheugh Gardens), Mr Laurence O'Shaughnessy: Surgical Revascularisation of the Heart

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane Road, W 12

TUESDAY—4.30 P.M., Sir Arthur Hall. Meningitis and Acute Infections of the Central Nervous System

WEDNESDAY—NOON, clinical and pathological conference (medical) 2 P.M., Prof J H Dible The Pathology of Liver Disease 3 P.M., clinical and pathological conference (surgical)

THURSDAY—2.15 P.M., Dr Duncan White: radiological demonstration 3.30 P.M., Dr A. A Moncrieff: Hygiene of the Newborn Child

FRIDAY—2 P.M., clinical and pathological conference (obstetrics and gynæcology) 2.30 P.M., Mr J B Hume Hernia and its Treatment

Daily, 10 A.M. to 4 P.M., medical clinics, surgical clinics and operations, obstetrical and gynæcological clinics and operations

ST GEORGE'S HOSPITAL, S.W 1.

THURSDAY—5 P.M., Dr A B Stokes: psychiatric demonstration

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, W.C 1

THURSDAY—2 P.M., Dr Wilfred Sheldon. Cow's Milk and its Modification in Infant Feeding 3 P.M., Mr Eric Lloyd Diseases of the Hip-joint in Children

Outpatient clinics daily at 10 A.M. and ward visits at 2 P.M.

FELLOWSHIP OF MEDICINE AND POSTGRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W.1.

MONDAY to SATURDAY—All Saints' Hospital, Austral Street, West Square, S.E 11, afternoon course in urology

Appointments

BRITTON, C J C, M.D N.Z., pathologist to the Samaritan Free Hospital for Women, N.W 1

BURKITT, DENIS, F.R.C.S.E., resident surgical officer at the Prince of Wales's Hospital, Plymouth

CLARKSON, J R, B.Sc Lond., consulting physicist to the Royal Northern Hospital, N 7

COGSWELL, A P L, M.B Lond., assistant deputy coroner for Central London

HAMILTON, ALISON M, M.B Edin., assistant bacteriologist in the public health laboratory, King's College, Newcastle-on-Tyne

KANDER, H S, M.R.C.S., registrar to the ear, nose, and throat department, Queen Mary's Hospital for the East End, E 15

LAMBERT, V F, Ch.M Manc., honorary assistant aural surgeon to the Manchester Royal Infirmary

LYTH, CONSTANCE, M.F., M.B Manc., resident medical officer at the Royal Manchester Children's Hospital

MEADOWS, S P, M.D., M.R.C.P Lond., honorary assistant physician to the Maida Vale Hospital for Nervous Diseases, W 9

NATHAN, H A, M.R.C.S., temporary assistant medical officer, Epsom

NORRISH, R E, F.R.C.S., assistant surgeon to the Albert Dock Hospital, E 16

WEBB, W L, M.B Lond., temporary assistant medical officer of health for the city of Westminster

Carshalton and District War Memorial Hospital—The following have been appointed honorary medical officers—

BLOOM, HAROLD, M.R.C.S.,
DRURY, E W, M.B Leeds, and
MAITLAND, H L C, Ch.M Sydney

Glasgow Corporation—The following have been appointed assistant medical officers to the police force—

BLACK, JOHN, M.B Glasg.
FITZ SIMONS, A B, M.B Belf. and
WALKER, R N, M.D Glasg.

Examining Surgeons under the Factories Act, 1937: Dr E C HARBOTTLE (Montrose District, Angus), Dr R. C B HALL (Llansawel District, Carmarthen), Dr A R MCWHINNEY (Stratford-on-Avon District, Warwick), Dr D W D MACLAREN (Golspie District, Sutherland)

Vacancies

Births, Marriages and Deaths

BIRTHS

ANNING.—On June 25, at Leeds the wife of Dr R. M Anning of Ripon—a daughter
BARTON.—On June 26 at Welbeck Street, to Dr Mary Barton, the wife of Dr Douglas L Barton of Morden—a daughter
CAPPS.—On June 19 at Park Square East, Inner London N W 1, the wife of Mr L C W Capps F R C S.—a daughter
COATES.—On June 22, at Westminster Hospital the wife of Dr Richard Coates of Edenbridge—a son
DILL-RUSSELL.—On June 25 at Nicosia Cyprus the wife of Dr P Dill Russell—a daughter
EVANS.—On June 23, at Tunbridge Wells the wife of Dr W O Evans—a daughter
KAY.—On June 23 at Sylvan Avenue Mill Hill, the wife of Dr E J S Kay of Borehham Wood—a son
KITSON.—On June 24 at Melton, Suffolk, the wife of Dr W Brooks Keith—a son
ROBERTSHAW.—On June 20, at Douglas Isle of Man, the wife of Captain G M Robertshaw, R A M C.—a son

MARRIAGES

KETTLE—DREW.—On June 24 at St Paul's Church Weston super Mare, Austin Braybrooke Kettle, M D, to Dorothy Mary Drew
LEIDHAM GRIFFN—CALDWELL.—On June 24 at St Peter's Church Burnham Bucks John Charles Leidham Green F R C S, to Gertrude Mary Somerville Caldwell M B

DEATHS

HAYLOCK.—On June 23 at Dreitwich Sydney John Haylock M R C S, of Southbourne, Bournemouth

N.B.—A fee of 1s 6d is charged for the announcement of Births, Marriages and Deaths

---

VALEDICTORY.—We part this week with the senior member of the staff Mr F W White, who has been editorial secretary since August 10 1901 He has contributed to our columns many informative notes His memory goes back to the Wakley tradition and many of our contributors are unknowingly indebted to his unrivalled knowledge of medical names and terms for their immunity from painful slips and omissions All his colleagues on the staff are aware of their debt and wish him God-speed in his retirement

NOTES, COMMENTS, AND ABSTRACTS

THE PHYSIOLOGY OF MARITAL INTERCOURSE

AN INQUIRY

BY J. R. GROOME, M.A., B.Sc. Oxfd

(From the Department of Zoology and Comparative Anatomy, Oxford University)

THREE married professional men, living in the south of England, undertook to keep accurate notes of their sex-life for 15 months. Much of the data so obtained is necessarily subjective; but it was hoped that accurate detail from a small source over a long period might be of greater value than replies to a general questionnaire. Wider verbal inquiries indicate some measure of agreement in matters which are susceptible to corroboration.

This inquiry was originally intended as a study of *the prostate gland in young men; the ancillary* findings cannot form a basis for comparison with the statistical data of Pearl (1925) on the frequency of coitus, or that of Engle and Shelesnyak (1934) on the menstrual cycle, as the method of approach is different, but they may be complementary to those works.

At the beginning of the inquiry the investigators were:—

1. Age 25, wife 26, married 2 years, 0 children.
2. Age 30, wife 32, married 6 years, 1 child.
3. Age 36, wife 33, married 10 years, 2 children.

All use contraceptives.

THE MENSTRUAL CYCLE

The average length of the menstrual cycle in the wives of these three men was 25·6 days, and the average number of copulations in each intermenstrual period was 6·2. From April to September the menstrual cycle occupied 26·3 days with 7·3 copulations; from September to April it occupied 25·1 days with 5·7 copulations. That is to say, throughout the summer there was an average of one copulation every 3·6 days, and throughout the winter one every 4·4 days.

Periods of desire seem to be infinitely variable, but the three women under consideration agreed fairly well. It seems in these cases that desire is at its lowest during the 6 or 7 days preceding menstruation; it rises steeply during menstruation and reaches a peak 2 days after menstruation has stopped. Desire then decreases slightly for 4 or 5 days; it increases again in the next 4 days and reaches a second, but less intense, peak. This second peak usually occurs 14 days after the beginning of the preceding menstrual period and is presumably associated with ovulation (Horrenbergen 1928). After this desire decreases, reaching its minimum a week before the beginning of the next menses.

This variation in desire is shown graphically and arbitrarily in the figure, with the copulations of no. 2 marked on the curve. A line has been drawn separating the curve into two portions of equal duration in each intermenstrual period. Where the curve is above this threshold line it represents a period of desire; where it is below the line a period of indifference.

During the 15 months of this inquiry there was an average per married couple of 70 copulations in the desire period, and 49 in the indifferent period. From April to September there were 4·6 copulations in the desire period and 2·6 in the indifferent period of each menstrual cycle; throughout the winter the figures were 3·0 in desire and 2·7 when indifferent. This, in conjunction with the greater frequency of coition, suggests that desire in women is more intense in warm weather, which agrees with the general evidence from the tropics.

The women also report an increase in the hip, waist and breast measurements six or seven days before menstruation begins, returning to normal when menstruation ends. This can hardly be comparable to the cyclical changes in the sexual skin of primates (Krohn and Zuckerman 1937, Zuckerman 1937), for in monkeys the swelling is in the follicular phase. It is, however, possible that there are similar metabolic changes, involving the utilisation of extraneous water. In women this increase, which is associated with sexual indifference, is doubtless a corollary of pseudopregnancy. Both pseudopregnancy and the indifferent phase are terminated by menstruation.

The fact that these women experience greatest desire at a time in the menstrual cycle when conception is unlikely may lend some support to Zuckerman's theory of the evolution of the family unit.

THE SEMEN

When rubber sheaths were used the volume of the ejaculate was measured. For the purposes of this inquiry an ejaculate of less than 3 c.cm. is called small, of 3–4 c.cm. medium, and of more than 4 c.cm. large. Ejaculates of medium volume were most common.

It was found that the amount of the ejaculate was not necessarily proportional to the length of the period of abstinence preceding it, although abstinence for 7 or more days usually ended in an ejaculate of more than 4 c.cm., and ejaculates of less than 3 c.cm. usually followed three copulations in the preceding 4 or 5 days. Volume was apparently unaffected by the common cold, but was much reduced after a fever.

The semen may contain solid bodies known as prostatic concretions, which are small concentrically marked grains staining with iodine, apparently formed in the alveoli of the prostate. Sometimes they are partly calcified and are then called prostatic sand. Large squamous cells of unknown origin may also be found in semen. These bodies are collectively referred to as debris. I am indebted to Dr. J. R. Baker and his assistants for assessing the debris and counting sperms in samples from one investigator (see Baker, Ranson and Tynen 1937). They found that washed sheaths must be used if the debris is to be assessed accurately, as the concretions are almost indistinguishable from the starch grains with which sheaths are dusted.

The amount of debris is very variable in different people and also in the same person at different times. A large amount of debris is not associated with a large ejaculate, and is therefore not produced as a result of high internal pressure in the ducts and glands nor is it associated with a small ejaculate, so that it does not seem to indicate an effort by the glands to produce a certain minimum of secretion. A large amount of debris is most usually found in the normal medium-sized ejaculate.

One investigator (no. 2) normally produced 162 million sperms per c.cm. of semen. In August he

contracted a streptococcal infection akin to scarlet fever The fever lasted a week, and three weeks later, with four ejaculations intervening, the fifth ejaculation contained so few sperms and was so small in volume that the sample was useless for experimental work Unfortunately no accurate assessment of the number of sperms was made It seems, however, that a febrile illness may result in temporary sterility

In the following winter this same investigator, aged 30, endeavoured to induce sterility artificially His body-temperature taken in the groin was 36 6° C In the morning before getting out of bed his average scrotal temperature was 31 3° C , in the evening it was 33 0° C For the 5 weeks of the experiment he wore, during the day only, a suspensory bandage containing three layers of thermogene wool This raised the evening temperature of the scrotum to 35 4° C The morning temperature was also found to be higher than normal, presumably as a result of increased blood supply, the average being 35 3° C

If spermatogenesis is slowed down or stopped the number of sperms in the semen will fall in proportion to the number of ejaculations that have taken place since the inhibitory condition started Conversely, when spermatogenesis is restarted or its rate increased the number of sperms in the semen will probably increase in proportion to the time between such restarting or increase and ejaculation

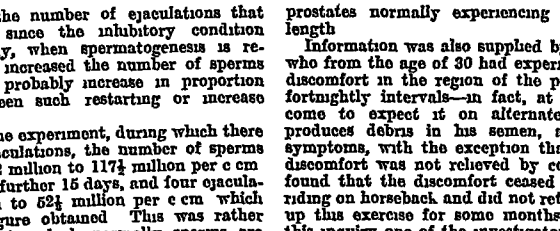
After 9 days of the experiment, during which there had been three ejaculations, the number of sperms had fallen from 182 million to 117½ million per c cm of semen After a further 15 days, and four ejaculations, it had fallen to 52¼ million per c cm which was the lowest figure obtained This was rather a small ejaculate, in which normally sperms are relatively more numerous, and represented an ejaculation of only 115½ million sperms, whereas this man's normal total is 637 million After a further 10 days and two ejaculations the number of sperms rose to 244 million per c cm and the next ejaculate in 3 days' time gave 215 million per c cm Throughout the experiment the epididymis on both sides appeared to be enlarged, but the increase was presumed to be entirely vascular

It seems from this experiment that an average increase in scrotal temperature of 1 7° C, is sufficient to discourage spermatogenesis for a short time After 4 weeks the testes become acclimatised and spermatogenesis proceeds more actively than usual Possibly more conclusive results could be obtained in the summer As bed clothes keep the scrotum more than 1° C warmer than trousers, it is possible that a non febrile disability, such as an accident which keeps the patient in bed, may result in a temporary reduction of fertility

THE MALE CYCLE

Two of the investigators experience considerable discomfort in the lower abdomen and region of the rectum from time to time The condition will normally disappear in a few hours, but may recur the next day or in two days' time It is relieved almost at once by copulation The frequency of urination is increased when this sensation is present but it is not affected by the condition of the bowel It was most marked in April, May and June It seems probable that this discomfort originates in the prostate, but I do not know whether it is normal or pathological The youngest of our three investigators never experienced it, and on wider inquiry most of the men who were asked either did not know it or would not admit to it It may only arise in prostates with a tendency to produce debris, but it was not as a rule associated with an ejaculate containing a large amount of debris

Prostatic discomfort was usually evident in investigators 2 and 3 at intervals of from 28 to 10 days, the mode being 19 days There was, however, one gap of 59 days and another of 71 days in which the discomfort was not evident These gaps are not incompatible with an ill defined cycle of 19 days, and it is suggested that they represent three and four periods respectively, which were missed, in prostates normally experiencing a cycle of this length



Arbitrary curve showing periodic variations in desire of the wife of no 2 Copulations are marked on the curve

Information was also supplied by Dr X, aged 38, who from the age of 30 had experienced fairly acute discomfort in the region of the prostate at regular fortnightly intervals—in fact, at one time he had come to expect it on alternate Thursdays He produces debris in his semen, and confirms the symptoms, with the exception that in his case the discomfort was not relieved by copulation Dr. X found that the discomfort ceased when he took to riding on horseback and did not return when he gave up this exercise for some months At the end of this inquiry one of the investigators bought a horse and the symptoms ceased when he rode; but they returned when the horse went lame and could not be ridden It has been suggested that this recurrent discomfort may be due to a vascular congestion, which is dissipated by what amounts in effect to massage, it should therefore be mentioned that investigators 2 and 3 and Dr X have no hæmorrhoidal tendencies

All three investigators reported a less acute sensation, which gives the impression of pressure in the epididymides or vasa deferentia or in both It may be bilateral or unilateral, and when present in the epididymis this organ appears to enlarge It was first noticed by one of the investigators, before his marriage, as a very acute pain in the vasa deferentia It would occur after periods of ungratified sexual excitement, such as a day spent in the company of his fiancée Since marriage, in this case, as with the other investigators, this so called spermatic colic has appeared as a mild discomfort at intervals

Spermatic colic is often associated with an ejaculate containing much debris, it sometimes accompanies prostatic discomfort, only once in the present investigation was it noticed to be associated with a small volume of ejaculate, it may arise on two

successive days in spring and summer, or with an interval of as much as 52 days in winter. Spermatic colic does not always follow abstinence, as might be expected if it is due to pressure in the ducts; in fact it often comes on at times when intercourse is frequent, but it is not possible to say that one is the cause of the other. In one case it was noted that spermatic colic was felt 18 times in the wife's period of desire and 11 times in the indifferent period. In the summer months, when desire was more apparent, it was noted 9 times in the desire period and only 3 times in the indifferent period, which suggests that its cause may not be entirely physiological.

Inquiry disclosed that spermatic colic, though not universal, is a much commoner symptom than prostatic discomfort. It is evident that the two phenomena are not associated.

A prostatic cycle, probably under the influence of the pituitary body and the testes, is not an impossibility in view of recent work on mammalian intersexuality.

SUMMARY

The marital sex-life of three young professional men was investigated for 15 months. Sexual activity was more apparent in summer than in winter.

Certain prostates seem to undergo cyclical changes occupying 2–3 weeks and involving physical discomfort. This cycle may only be noticeable in prostates producing debris; it may be pathological. Riding a horse was found to allay the symptoms.

Spermatic colic is often associated with the presence of prostatic debris, but the ultimate cause may be psychological, as the presence of debris is not universal.

Spermatogenesis is probably checked by fever. It was also checked by raising the temperature of the testes artificially, but proceeded normally when these had become acclimatised to the new conditions.

I am indebted to my three anonymous collaborators and to Dr. J. R. Baker for much helpful comment.

MEDICAL ORATIONS

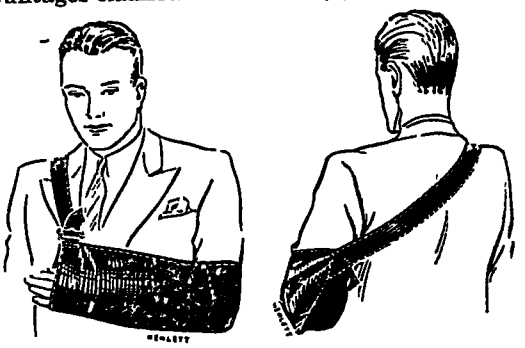
A REPUTATION as a medical orator is an unhappy possession, for at least three or four times a year its possessor must face an audience which demands an exhibition of oracular wisdom. In his "March of Medicine" (London: Humphrey Milford, Oxford University Press. 1938. Pp. 280. 12*s.* 6*d.*) Dr. Lyman Wilbur of California has collected 29 of these Delphic utterances delivered by him between 1913 and 1937. They are quite characteristic. The glowing past and radiant future of our profession are painted in the routine colours. No doubt this is what congresses like, or why should Dr. Wilbur have been called on time and again? These addresses could certainly hurt nobody's feelings, but they will leave most readers cold.

SULPHANILAMIDE IN TULARÆMIA

Dr. Henry G. Hadley, of Washington, D.C., informs us that he has noted clinical improvement in a patient with tularæmia treated with sulphanilamide. The patient, a white female, aged 29, was seen on Nov. 28, 1938, having a shallow ulcer on the right index finger with a greyish slough and associated with enlargement of the epitrochlear and axillary glands. The finger had been injured two weeks earlier while she was dressing a rabbit. The illness began four days later with sudden onset of chill and fever, and she was confined to bed for a week and treated for influenza. On Dec. 1 the serum gave a positive test for tularæmia, 1 in 27 dilution. Sulphanilamide gr. 30 was given daily from Dec. 4 to Dec. 8 and was discontinued temporarily because of a general eruption. It was started again as soon as the rash had disappeared, and from Dec. 22 to Jan. 4 she received gr. 30 daily. The enlargement of the glands had almost entirely subsided and the finger lesion had entirely healed by Jan. 4. During both periods of sulphanilamide therapy improvement was noted subjectively and objectively, and while it was discontinued the patient's condition remained relatively stationary.

AN ARM-SLING

C. J. HEWLETT & SON, LTD., send us the accompanying sketch of the "Mead" adjustable arm-sling. The advantages claimed for it are: (1) it can be used for



either arm; (2) the weight is carried by the shoulder and not by the neck; (3) it is readily adjustable by means of a non-slipping buckle; and (4) it is light and washable. Messrs. Hewlett's address is 34, Charlotte Road, London, E.C.2.

MANUSCRIPTS AND ENGRAVINGS

AMONG the manuscript treasures which Messrs. Sotheby are to offer for sale next month is a thirteenth-century copy of Albuhasim De Chirurgia, bound up with other medical works and illuminated with miniatures and drawings of instruments. It affords an example of the fleeting character of human fame, for it is by the beauty of the setting alone that Albuhasim's work has survived the lapse of ages. Great in his generation he now lives only by the patient and devoted work of an unnamed English scribe. The same train of thought is suggested by Messrs. Suckling's catalogue of engraved portraits of scientists. In their lives or after their deaths these men climbed at least the first slopes of the hill of Fame, yet to us their representations are chiefly valued not for the memorial of what they accomplished but for the beauty and vigour of the—often unknown—artist's work.

REPRINT OF HIPPOCRATES

"Adams, of Banchory (a little Aberdeenshire village), was not only a good practitioner and a skilful operator but he was an excellent naturalist. This is by no means an unusual or remarkable combination, but Adams became in addition one of the great scholars of the profession. He had a perfect passion for the classics. . . . He translated the works of Paulus Aegineta, the works of Hippocrates, and the works of Aretaeus . . . monuments of the patient skill and erudition of a Scottish village doctor." So wrote Osler in one of those papers in which he delighted to praise our forefathers. The Sydenham Society published Adams's translation of Hippocrates in 1849, and now, nearly a century later, his work has been reprinted by Baillière, Tindall and Cox in a neat volume (The Genuine Works of Hippocrates. London. 1939. Pp. 384. 13*s.* 6*d.*) which reproduces the text with few modifications, but omits much of Adams's notes and illustrations.

ADDRESSES AND ORIGINAL ARTICLES

ACUTE OBSTRUCTION OF THE SMALL INTESTINE*

BY R L HOLT M D Manc, F R C S
HON SURGEON TO THE MANCHESTER NORTHERN HOSPITAL

EXPERIENCE has proved that the treatment of acute intestinal obstruction is not merely a matter of surgical technique When the condition is recognised and treated in its early stages, the results are very satisfactory, but in the later cases, when the bowel has become damaged and systemic effects have manifested themselves, the relief of the obstruction is often not sufficient to prevent a fatal termination The fundamental importance of early diagnosis and treatment cannot be emphasised too strongly, but for a variety of reasons many cases are seen by the surgeon for the first time several days after the onset Even under modern conditions these cases have a mortality rate of about 60 per cent, and their treatment presents a most serious problem to the surgeon In one of his earlier articles the late Sir David Wilkie said that "any advancement in the treatment of acute ileus must be based on a more exact understanding of the relative importance of the various factors which make for a fatal issue in this malady" The immediate cause of death in human patients is often some obvious complicating factor, such as peritonitis or pneumonia, and the real difficulty is to explain the severe illness in the earlier stages

The causes of intestinal obstruction have been the subject of detailed study in the past, and much valuable information has been gained, but in acute obstruction the cause is not so important as the effects It is only by learning to treat the effects as well as the cause that any improvement in the treatment of obstruction is to be hoped for The local and general effects have been investigated by numerous research workers in the last twenty or thirty years, and it is now possible to give a *fairly accurate* account of the *physiopathology of acute obstruction* The object of this paper is to recount briefly the information which experimental work has provided and to indicate the lines along which this knowledge can be usefully applied in clinical practice

DEFINITION

Intestinal obstruction is divided into two types—mechanical and paralytic In mechanical obstruction the contents of the intestine are prevented from passing along by an actual obstruction to the lumen of the gut In paralytic obstruction the contents do not pass along because the intestinal muscle cannot provide the necessary propelling force Mechanical obstruction is customarily divided into simple obstruction and strangulation In simple obstruction there is a complete obstruction to the passage of the intestinal contents, and in strangulation there is, besides the obstruction of the lumen, an obstruction to the blood supply of the obstructed gut The distinction is not always clear cut Uncomplicated obstruction is rare clinically, for many cases which begin as an obstruction pass in their later stages into a condition which shows some of the elements of strangulation

OBSTRUCTION

The function of the duodenum is primarily one of secretion, whereas that of the ileum is one of absorption The volume of digestive fluids poured daily into the duodenum and absorbed at a lower level in the intestinal tract has been estimated at 5–7 litres An obstruction in the upper part of the small intestine prevents the reabsorption of these secretions, which accumulate and distend the gut above the obstruction Peristaltic activity is stimulated by the distension, and, besides causing the typical colicky pain of obstruction, the accumulating fluids are forced up into the stomach, from which they are vomited. Obstructions in the duodenum or upper jejunum are manifested by profuse vomiting, producing a continual loss of digestive secretions When the lower part of the small intestine is obstructed, the picture is somewhat different Occasionally such cases are marked by the early onset of profuse vomiting, but usually vomiting is not a feature in the early stages, because the ileum is able to absorb the greater part of the fluids passing down to it from the duodenum and jejunum If reabsorption were complete, the signs and symptoms of obstruction would be absent, but usually absorption is incomplete, and a slowly progressive distension develops The capillary and venous circulation is interfered with, giving the gut a congested appearance, there are submucous hæmorrhages, and patches of necrosis are found in the mucosa, especially on the antimesenteric border The intestinal wall becomes thickened by plasma exuded from the capillaries, and from the same source comes the plasma like peritoneal fluid The intestinal muscle, perhaps as the result of overstretching or œdema, loses its tone and contractile power, tending to produce a partial or complete paralysis of the gut immediately above the obstruction In such a way are produced the heavy thick-walled, distended, and congested loops of small intestine so often seen at operation

There are two main types of obstruction high obstruction marked by profuse vomiting and loss of fluids, and low obstruction marked by progressive intestinal distension which causes severe local effects in the obstructed gut Originally it was thought that the absorption of toxic substances from the foul contents of the obstructed loops of gut was the cause of death in all cases of obstruction There was no difficulty in demonstrating the toxic qualities of numerous substances extracted from the contents of obstructed gut, but the general application of this theory had to be limited when it was shown, firstly, that animals with a high intestinal obstruction could be kept alive for long periods by the administration of sufficient quantities of normal saline, and, secondly, that normal intestinal mucous membrane prevented the absorption of these toxic products There is general agreement among experimental workers that death in high intestinal obstruction is due not to toxæmia but to the progressive dehydration that results from the profuse vomiting Toxæmia, however, is still held by most writers to be the cause of death in low obstruction In these cases several investigators have not been able to prolong the lives of their animals by the administration of saline In low obstruction degenerative changes in the mucosa of the obstructed loops of gut are usual, and it is alleged that these changes remove the normal protective barrier Even so there is no direct evidence of such absorption Many experiments have been

* A paper read to the Manchester Surgical Society on Nov 15 1938

carried out with various readily recognisable substances, such as strychnine and methylene-blue, but the bulk of the evidence points unmistakably to the fact that, under the conditions existing in low obstruction, absorption from the intestine is actually diminished It was with the idea of clearing up this problem that most of my experiments on obstruction have been concerned. They prove conclusively that toxic absorption is not a factor in low obstruction It has been shown that animals given sufficient saline always live for three to four weeks unless the gut perforates above the obstruction and peritonitis sets in. The fact that the administration of saline in sufficient amount controlled the systemic effects of obstruction suggests that whatever these effects are they act by causing dehydration and secondary changes in the circulation

Some explanation other than toxæmia is therefore necessary to account for the severe illness of patients with low intestinal obstruction. One fact has been clearly demonstrated experimentally in these cases—namely, that if distension of the gut is prevented the signs and symptoms of obstruction do not develop. The effects of distension of the gut are as follows:—

(1) *Reflex*: (*a*) vomiting; (*b*) increase in the secretions from the intestinal glands; (*c*) anorexia; and (*d*) pressor impulses.

(2) *Local*: (*a*) stasis of blood and œdema in the walls of the obstructed gut; and (*b*) partial or complete paresis of the intestinal muscle.

The first five factors have one common effect: direct or indirect dehydration of the body tissues and reduction of the blood volume. Vomiting and increased glandular secretion tend to drain the tissues of water and salts, and anorexia prevents their replacement. The pressor impulses, by maintaining a reflex vasoconstriction, tend directly to reduce the blood volume Finally, the changes in the intestinal wall are very important. The stasis of blood in the vessels, the plasma exuded into the tissue spaces, and the peritoneal exudate remove plasma and whole blood from active circulation. The importance of this factor depends on the length of gut in which these changes are found. When approximately half of the intestine is affected, it has been estimated that the volume of blood and plasma removed from circulation amounts to 20–30 per cent of the initial blood volume

All these factors play their part wherever the obstruction is situated in the small intestine, and the predominance of one or other explains the variability of the symptoms. In obstruction of the duodenum profuse vomiting is the most pronounced symptom, and sufficient fluid and salts may be lost to cause death from dehydration. In consequence an examination of the blood shows a reduction in the chloride value and a lowering of the blood volume In low obstructions vomiting is not so profuse and may be absent for several days. It is only in those patients who vomit profusely that there is any rapid deterioration in the general condition. It is in low obstruction that the effects of the factors of limitation of intake of fluid and salts and the loss of plasma and whole blood into the distended gut are seen It is sometimes suggested that the dehydration of the patient is greater than can be accounted for by the fluid lost by vomiting and into the obstructed loops of gut. The volume of fluid normally lost daily by the average patient has been estimated to be about 4000 c.cm.: 2000 c cm. by perspiration and by vaporisation in the breath; 500 c cm. by the intestinal tract; and 1500 c.cm. by the kidneys excreting urine at a specific gravity of 1 015.

The loss by perspiration and respiration, the so-called insensible loss, continues until sufficient fluid has been lost to equal 6 per cent of the body-weight, by which time signs of dehydration are evident. In low obstruction the replacement of this fluid is quite inadequate, and, if to this loss are added the fluid lost by vomiting and into the loops of gut and the blood and plasma withheld from the circulation, it becomes evident that a very severe dehydration may result from the combined effects of these losses In my opinion these losses are the direct cause of the poor general condition of patients with a low intestinal obstruction. In some cases the effects of the severe dehydration are sufficient to cause death, but in other cases, although the patient is reduced to a very low state by the dehydration, death is due to peritonitis or such a terminal complication as bronchopneumonia.

STRANGULATION

The occurrence of strangulation adds a most serious complication to intestinal obstruction. Theoretically it is possible for both the arteries and the veins of a strangulated loop of gut to be obstructed, but in practice only the veins are obstructed The effect of such venous obstruction is that the tissue spaces become filled with red cells, the lumen of the gut is distended with a thick red exudate, and a fluid indistinguishable from plasma exudes from the peritoneal surface of the gut. The organisms in the lumen proliferate and invade the bowel wall, the tissues of which disintegrate progressively until ultimately perforation takes place. In experimental strangulation the survival period and the cause of death depend on the length of gut involved in the strangulation. The experimental long-loop strangulation is chiefly of academic interest, since strangulation of loops of such length in man must be rare. In animals the strangulation of half or more of the small intestine causes what is to all intents an acute internal hæmorrhage. This blood loss may, however, be important in certain cases of acute intussusception, volvulus, and mesenteric thrombosis Strangulation of even so-called moderate-sized loops, such as are used experimentally, in which about a quarter of the small intestine is strangulated, does not often take place in man In these cases the passage of blood into the tissues of the strangulated loop does not continue indefinitely, for after a time thrombosis occurs in the capillaries and smaller veins. Attention is turned to the fluid exuded from the strangulated loop At first indistinguishable from plasma, the fluid soon becomes darker and develops depressor qualities when injected intravenously. The depressor substance present in the early samples is akin to histamine Later the fluid becomes almost black and acquires the odour characteristic of gangrenous gut. This later exudate is very toxic and, if injected intraperitoneally in sufficient quantity, will kill normal animals The exact nature of this toxin is not known, but it is akin to the proteoses and is produced by the action of proteolytic bacteria on the tissues of the intestinal wall. In animals with a strangulation of a quarter of their small intestine the cause of death is the absorption of this toxic exudate from the peritoneal cavity. The fact that toxic substances are produced in the tissues of strangulated gut and pass into the peritoneal fluid shows the importance of handling the strangulated loops as little as possible

within the peritoneal cavity and of removing the peritoneal fluid by suction

The short loops used experimentally are similar to those which are most often strangulated in clinical practice In these cases perforation of the loop is always found at autopsy, and peritonitis is the cause of death, but perforation does not necessarily cause a widespread virulent peritonitis This is especially true when, instead of the gut perforating suddenly and flooding the peritoneum, there is a gradual seepage of the contents through the gangrenous wall of the gut This fact is illustrated by two cases from my practice which came to operation with the pre operative diagnosis of a pelvic peritonitis of uncertain origin Both patients had been ill three days before being sent to hospital. In each case about 2 ft of collapsed gangrenous small intestine was found to be the cause of the peritonitis, and both patients survived a resection and anastomosis with little apparent difficulty I do not wish to imply that the factors of blood loss into the strangulated loop and the absorption of toxic exudate are unimportant It is true that they are not the immediate cause of death in short loop strangulation, but they are present and help to undermine the general condition of the patient Most strangulations in clinical practice take place in hernial sacs The constriction at the neck of the sac and the adhesions that form there not only delay absorption of any exudate but also tend to localise the infection that follows perforation of the loop Such patients can therefore survive for longer periods than would be the case if the strangulation had taken place in the general peritoneal cavity It is in these cases with their larger survival period that the effects of the intestinal obstruction, which always accompanies a strangulation, become pronounced It is possible to recognise cases in which the effects of the strangulation itself predominate and others in which the effects of the accompanying obstruction appear the more important

TREATMENT

The two factors which adversely affect the treatment of acute obstruction are (1) delay in instituting treatment and (2) the presence of strangulation

The time factor in the treatment of acute obstruction is most important Delay allows the systemic and local effects of the obstruction to add serious operative and postoperative risks In the early case the relief of the obstruction cures the patient, but in later cases similar treatment often does not prevent a fatal result It is in the treatment of these later cases that considerable improvement is possible by applying the information which experimental work has produced In the absence of strangulation there is no toxæmia, and the poor condition of the patients is the result of the systemic effects of intestinal distension The systemic effects, apart from lowering the general condition of the patient and rendering him more than usually susceptible to postoperative complications, make administration of an anæsthetic risky It is not generally realised how great the dehydration may be, though some clinical indication of this is provided by the sunken eyes and shrinkage of the subcutaneous tissues The dehydration of the tissues is well advanced before the blood volume is reduced It is easy to be misled by an apparently normal systolic blood pressure and only slightly raised pulse rate These cases of obstruction provide some of the commonest examples of the condition that Zachary Cope has described as latent shock The pulse pressure and pulse rate may remain normal after the blood volume is considerably reduced In fact this variety of shock may be accompanied by a rise in blood-pressure which is merely an overcompensation to a circumstance which tends to cause a fall of blood pressure The whole of the mechanisms by which the body attempts to maintain an efficient circulation have been mobilised Many of these are nervous mechanisms and are easily put out of action by an anæsthetic Serious or fatal results may follow the administration of an anæsthetic unless measures are taken beforehand to restore the blood volume

When the possibility of strangulation does not enter into the diagnosis, there is no overwhelming urgency to hurry the patient into the operating theatre At least two or three hours can be profitably spent in carrying out a routine preoperative treatment In general it can be said that the more pronounced the dehydration the longer this pre operative preparation should be In the late cases the relief of the obstruction is not so important as the adoption of measures to relieve the intestinal distension and to replace some of the fluid lost If these measures are not carried out adequately, it will be found that many patients "peter out" within twenty-four hours of operation The patient should be treated along the usual "anti shock" lines—i e, thoroughly warmed with hot blankets or bottles, given an injection of morphine, and transfused with saline administered by a continuous intravenous drip About 1000 c cm of normal saline should be given to the average patient before operation, but, if more than two or three hours is taken over the preoperative preparation because of severe dehydration, the volume of saline should be increased Hypertonic saline should not be given, for its use is based on a mistaken conception of the importance of the loss of sodium chloride as the cause of the illness The stomach must be emptied, preferably by a Ryle's or similar tube, which ought to be left in position during and after the operation With such measures the patient's general condition is found to improve considerably, and operation may now be more safely undertaken The anæsthetic of choice is unquestionably spinal anæsthesia but it is only safe if measures have been taken to restore the blood volume In strangulated hernia in very old patients local anæsthesia may be preferable to spinal anæsthesia The presence of several feet of thick walled, distended, and congested gut may tempt one to perform an enterostomy, but except in rare cases this is not necessary It has been found in practice that continuous siphonage of gastric and duodenal contents through a Ryle's tube is just as effective as an enterostomy, and its use does not carry with it the very real danger of peritonitis which an enterostomy introduces Some idea of the prognosis can be gained from the state of the gut above the obstruction If under spinal anæsthesia there is a segment of gut that does not show any muscular contractions, especially when stimulated by pinching, paralytic ileus is to be expected

When strangulation is suspected, the emptying of the stomach and the administration of intravenous saline must be hastened and operation carried out as soon as possible No delay is justifiable, because of the danger of viable gut becoming gangrenous Certain precautions are suggested by experimental work The abdominal incision should be large enough to allow the strangulation to be freed rapidly The excessive manipulation of strangulated loops within the peritoneal cavity is dangerous, for it is likely to increase the amount of toxic products passing into

the peritoneal fluid The peritoneal fluid should be removed by suction while the viability of the strangulated gut is being decided. In no circumstances should gut about which there is any doubt of viability be returned to the peritoneal cavity, because of the very serious risk of perforation and peritonitis. For the same reason the oversewing of gangrenous constriction-rings in the gut is not without risk. If the patient's general condition does not warrant an immediate resection and anastomosis, the loop of gut should be exteriorised. It may be left in the subcutaneous tissues or on the surface of the abdominal wall and dealt with later

The treatment of acute intestinal obstruction does not end with a successfully completed operation. The measures begun before operation to remedy dehydration must be continued for several days after operation. One of the most serious effects of intestinal distension is the partial or complete paralysis of the intestinal muscle of the distended gut. Treated on the correct lines most of these cases settle down; but, if the gut is stimulated by purgatives and other drugs, a paralytic ileus often results. It is most important to regard and treat every case operated on for acute intestinal obstruction or strangulation as a potential case of paralytic ileus. Fluids should only be allowed very sparingly by mouth and in many cases prohibited altogether, unless continuous gastric siphonage is being carried out. Fluid is best given as normal saline by a continuous intravenous drip, but rectal and subcutaneous routes may be employed. About 4–5 pints daily is usually sufficient for an adult. Purgatives and drugs which normally stimulate peristaltic action are contraindicated The habitual use of such drugs as Pituitrin, eserine, and acetylcholine in the postoperative treatment of these cases is to be strongly condemned. Occasionally their use produces the dramatic relief of intestinal distension, but these successes are far outnumbered by the majority of cases which are made worse by such treatment. It should be borne in mind that the cause of the trouble is a paresis of the intestinal muscle which will resume its function when it has recovered its tone. This recovery is best facilitated by resting the gut as much as possible. It is for this reason that fluids by mouth are restricted or prohibited. Morphine is very valuable in these cases and should be given in small doses at regular intervals—e.g., gr. ⅛ four-hourly. If the case progresses satisfactorily, the abdominal distension gradually disappears and the bowels are naturally moved about the fourth day. After this the restriction on fluids by mouth may be withdrawn and treatment carried out along ordinary lines.

PARALYTIC ILEUS

There are many causes of paralytic ileus, but, so far as the surgeon is concerned, it most often complicates cases of peritonitis and of intestinal obstruction. It produces a painless progressive distension of the abdomen, which in the later stages is associated with vomiting and is apt to bring to a fatal ending what appeared to be a successful operation. It leads to a progressive circulatory failure along the lines outlined under mechanical obstruction. Its development can often be prevented by adopting the measures already described. Once it has developed, by far the most satisfactory method of treatment is one which has been described by American writers as "intestinal decompression." The principle of the method is the adoption of continuous mild suction through an indwelling catheter in the stomach or duodenum. A Ryle's or similar tube is passed through the nose or mouth and attached to an apparatus which provides a continuous slight suction, or aspiration with a syringe may be applied at short intervals. It has been shown that the intestinal tract can be drained as far as the ileo cæcal valve by such means. The patient obtains prompt relief from vomiting and from the discomfort due to abdominal distension It is preferable to allow fluids by mouth as soon as the apparatus is functioning, for this measure keeps the mouth fresh and gives much comfort to the patient. No harm is done, for the fluid is promptly siphoned back through the indwelling tube Careful note should always be kept of the volume of fluid given by mouth and of that removed by the tube In the early stages of treatment more fluid is removed than swallowed If the reverse happens, the stomach-tube is partially blocked or kinked. The fluid removed at first is usually brown foul-smelling contents of the small gut Later this changes to clear bile-stained fluid, and finally, as the intestine recovers its function, it is found that less fluid is removed by the stomach-tube than is taken by mouth Morphine is given in doses of gr. ⅛ four to six times daily. Fluid is supplied by a continuous intravenous drip in amounts of about 4–5 pints daily. Greater amounts should not be given, because of the danger of setting up œdema of the lungs and pneumonia. The condition is usually found to be resolving about the third or fourth day after treatment is begun. It is customary for the bowels to act naturally about the fourth day, if not, a glycerin enema is given. No purgatives or drugs such as pituitrin, eserine, or acetylcholine are to be given during the above treatment, for their use has been proved to aggravate the intestinal paresis.

The results of this treatment are extremely good. I have given up enterostomy completely since I began to use this method. In the past few years I have seen this treatment carried out in many cases of ileus In those cases which were not due to a peritonitis—they now mount up to about 30—there have been two deaths: one from pulmonary embolism and one from the results of the ileus In this latter case treatment was, in my opinion, instituted too late. The results in cases due to peritonitis are very encouraging but naturally not so satisfactory. The method of intestinal decompression relieves the abdominal distension and gives the patient a better chance to localise the peritoneal infection. But these cases have a way of slipping through one's fingers I can recollect three patients with ileus following appendicitis with general peritonitis who recovered from both the ileus and the peritonitis only to die from bronchopneumonia Such disappointments, however, do not detract from the value of the treatment.

CONCLUSIONS

Treatment of acute intestinal obstruction along the lines outlined is applicable chiefly to those cases in which there has been some delay in instituting treatment. For the very late case it is doubtful whether much good can be done. In these cases it appears that irreversible circulatory changes have taken place. There is a general increase in capillary permeability, and fluid injected intravenously rapidly passes out of circulation, carrying plasma proteins with it. They are usually described as inoperable, and sometimes a gallant attempt is made under local

anæsthesia to relieve the distension A good case can be made out for treating them by intestinal decompression and subcutaneous saline and making no effort to relieve the obstruction until the patient has obviously survived the systemic effects of the obstruction

The treatment outlined above has been based on an understanding of the general and local effects which follow the onset of acute intestinal obstruction I have no doubt that improved results will follow the general adoption of such measures, but any success which may follow must not be allowed to obscure the fundamental point in the treatment No understanding, however thorough, of the physiopathology of this condition will compensate for undue delay in treatment Early diagnosis and treatment must always remain the aim of the surgeon in dealing with acute intestinal obstruction

THE MECHANISM OF DIABETES MELLITUS *

By H P Himsworth, M.D Lond, F R C P
DEPUTY DIRECTOR MEDICAL UNIT, UNIVERSITY COLLEGE HOSPITAL, LONDON

II—THE CONTROL OF THE BLOOD-SUGAR LEVEL

In the different examples of variation in the blood sugar level which have been considered it has been possible to trace the workings of an underlying purpose that the head of pressure of sugar in the blood, in the circumstances existing at any particular time, is adjusted to maintain the adequate utilisation of sugar by the tissues The mechanism by which these adjustments in the head of pressure of blood sugar are brought about must now be discussed, but, before doing so, it is necessary to consider the effect of two factors absorption of sugar from the intestines, and removal of the blood sugar by the extrahepatic tissues, which do not appear to be directly concerned in this purposive adjustment

ABSORPTION OF CARBOHYDRATE FROM THE INTESTINE

It has been shown by Cori [24 25] and by Verzár [124] that absorption of glucose from the gut is an active and not a purely physical process When a solution of glucose enters the gut, absorption begins at a maximal rate and proceeds at this rate, irrespective of either the amount or the concentration of the glucose present, until all the glucose is absorbed These findings agree with the observation that the blood sugar tolerance curve of the healthy human subject is practically uninfluenced by increasing the dose of oral glucose above a certain minimal dose and are in accord with the constancy of the blood-sugar curve under standard conditions In fig 5 are shown two blood sugar tolerance curves after ingestion of a standard dose of glucose, which were obtained from a healthy but very nervous subject On the first occasion half an hour elapsed after the glucose was taken before any rise of blood sugar was detected. On the second occasion, after he had become accustomed to the test, the blood sugar rose immediately The area of each sugar tolerance curve after it began to rise is the same This experiment suggests that on the first occasion passage of glucose from the stomach to the intestines was delayed, but, when the sugar entered the intestines, absorption proceeded at the normal rate It is possible that absorption from the intestines proceeds on an "all or none" principle The tacitly accepted view that hyperglycæmia following ingestion of sugar is accounted for by the excess of absorbed sugar entering the blood has been questioned by Heténya. [33 36] Struck by the fact that after the ingestion of glucose the rise of blood sugar could often be detected within two minutes, he suggested that alimentary hyperglycæmia was largely due to reflex liberation of sugar from the liver Unfortunately no sure proof of this attractive hypothesis has been brought forward, but the hypothesis would certainly explain the purposive variations in the glucose-tolerance curve

In certain conditions, such as sprue and cœliac disease, a low blood sugar tolerance curve is obtained Fairley [39] and Ross [115] have recently shown that the intravenous blood sugar tolerance curve in such diseases is unusually high, and they have suggested that the characteristically low oral tolerance curve is produced by defective absorption If Heténya's hypothesis proves to be correct, it may well be that the low curves in sprue and cœliac disease are due to diminution in the amount of glycogen in the liver, in which case the hyperglycæmia after injection of adrenaline should be slight

In view of the constancy of glucose absorption from the gut and the constancy of the blood sugar tolerance curve in each of several standard sets of conditions (table I in Lect I) it appears that the factor of intestinal absorption plays little part in determining the blood sugar curve of persons without intestinal disease

REMOVAL OF SUGAR FROM THE BLOOD

The outflow of sugar from the blood may be due either to its escape into the urine or to its removal by the tissues It is commonly believed that, when the blood sugar level exceeds the renal threshold, the sugar which escapes into the urine materially reduces the blood sugar level The evidence presented in Lect I shows that, in ordinary circumstances, this *is not so* When, however, the loss of sugar in the urine is rapid and excessive, as is seen after poisoning with phloridzin, the blood-sugar level may fall, but only after the liver has made extreme efforts to conserve it at its normal level I believe that in all other conditions, save possibly diabetic coma, the blood sugar level is uninfluenced by

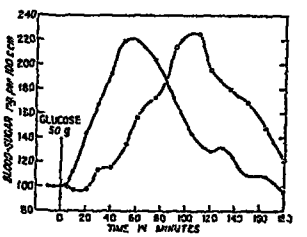


FIG 5—Two blood-sugar tolerance curves obtained from the same healthy subject when he was taking the same low-carbohydrate diet In one experiment the subject was nervous and the rise of blood sugar after ingestion of the glucose was delayed (circles), in the other experiment (disks) the rise was immediate Both sugar tolerance curves are nevertheless of the same size

* The Goulstonian lectures for 1939 delivered before the Royal College of Physicians of London on March 2 7, and 9 Lect I appeared in our last issue and the second part of Lect II and Lect III together with the references, will appear in later issues

glycosuria. In diabetic coma the demands on the liver for sugar may be so excessive that they can be met, if at all, only with difficulty. In these circumstances the augmentation of such demands by wastage of sugar in the urine may cause a demand on the liver for more sugar to which it cannot respond, with the result that the hyperglycæmia is not fully maintained.

It is also doubtful whether excessive utilisation of sugar from the blood by the peripheral tissues ever results in a fall of blood-sugar, for it is improbable that the rate of this utilisation ever exceeds the capacity of the liver to supply equivalent amounts of sugar to the blood In Graves's disease the total metabolism is increased, and, the proportions of the different foods oxidised remaining normal,[35] the peripheral utilisation of sugar must presumably be increased. Yet spontaneous hypoglycæmia does not occur, nor does the blood-sugar curve fall more rapidly. On the other hand, in diabetics who develop thyrotoxicosis this complication is accompanied not by a fall but by an elevation of the general level of hyperglycæmia, and with cure of the thyrotoxicosis this hyperglycæmia diminishes. When the peripheral utilisation of sugar is reduced or abolished in animals by poisoning with such substances as hydrocyanic acid[107] or iodo-acetic acid[76] or by lack of oxygen,[88] the blood-sugar rises. This, of course, may be due to the direct effect of such poison or of anoxæmia on the liver, but it may also be due to the reduction in ability of the tissues to oxidise carbohydrate, causing a condition of carbohydrate starvation of the tissues, in an effort to remedy which the liver pours out an excess of sugar into the blood. Reference can here be made to the conception of tissue storage of glucose developed by Soulá.[127] According to this conception, when an excess of sugar enters the blood-stream much of this diffuses into the peripheral tissues and then, as the blood-sugar falls, slowly returns to the blood. In conjunction with McNair Scott[70] I have obtained results compatible with the existence of a peripheral source of blood-glucose.

It is thus doubtful whether either the rate of absorption of sugar from the intestine or the rate of removal of sugar from the blood by the extrahepatic tissues plays a part in the adjustment of the blood-sugar level They appear rather as factors which, by influencing the movement of sugar into or out of the blood, call into play the active mechanisms which adjust the head of pressure of blood-sugar to the appropriate level.

MECHANISMS INVOLVED IN THE ADJUSTMENT OF THE BLOOD-SUGAR LEVEL

At the centre of the mechanism adjusting the head of pressure of blood-sugar stands the liver. It is the effector organ directly producing the compensatory variations in the blood-sugar level In hepatectomised animals the blood-sugar falls steadily until death results from hypoglycæmia, thus showing that in the fasting organisms the liver is constantly secreting sugar into the blood and so maintaining the blood-sugar at the appropriate level[90 91] In the liver carbohydrate is stored as glycogen, and this constitutes the source of blood-glucose. Liver-glycogen can be formed from materials other than glucose such as proteins, hexoses other than glucose, glycerol, and lactic acid. That the transformation of these substances to glucose in the intact animal is brought about by the liver is indicated by the fact that in the hepatectomised animal none of them can relieve hypoglycæmia.[91] It is still a controversial question whether liver-glycogen can be formed from fatty acids, but evidence is steadily accumulating in favour of this view.[122 139] The liver, therefore, not only secretes but manufactures glucose, and the rate at which these reactions of the liver proceed is largely governed by the various endocrine glands, the function of which may now briefly be reviewed.

PITUITARY GLAND

The association between disease of the pituitary gland and abnormal carbohydrate metabolism has been known since Pierre Marie recorded the frequent occurrence of glycosuria in acromegalics, and the more recent recognition by Cushing[29] of the frequency of glycosuria in cases of pituitary basophilism has strengthened the clinical evidence for this association The demonstration by Burn[17] that the extract of the posterior lobe of the gland, pituitrin, raised the blood sugar directed attention to the posterior lobe as the source of the disturbance of carbohydrate metabolism in these diseases, but recently the brilliant work of Houssay and his school has pointed attention to the anterior lobe. The large volume of work on the relationship of the anterior-pituitary gland to carbohydrate metabolism has been reviewed by Houssay[72 73] and by Russell,[117] and reference can be made to their articles for the extensive bibliography on this subject

The problem of the influence of the anterior-pituitary gland on the activities of the liver can best be approached by considering the effect of removing this gland on a condition with which we are already familiar. We have seen that, when a normal fasting animal is poisoned with phloridzin, the head of pressure of blood-sugar falls because of the drain of the excessive glycosuria, and in an attempt to maintain the head of blood-sugar pressure the liver pours sugar into the blood rapidly. This sugar is derived in the first place from the carbohydrate stored in the liver as glycogen and later, when this store proves insufficient, from sugar manufactured in the liver out of body protein and possibly out of fat The excessive breakdown of body protein is revealed by an increased excretion of nitrogenous substances in the urine; the excessive combustion of fat by the excretion of ketone bodies. When, however, a hypophysectomised animal is poisoned with phloridzin, the findings are quantitatively different in two important respects: the excretion of urinary nitrogen is little more than normal,[14] and ketonuria is either absent or minimal.[113] This indicates that in the hypophysectomised animal poisoned with phloridzin there is little acceleration in the rate of destruction of protein and of fat, and we can infer from this finding that after hypophysectomy the ability of the liver to form sugar from non-carbohydrate materials is impaired This effect of removing the anterior-pituitary gland is further illustrated by the influence of hypophysectomy on pancreatic diabetes. Soon after removing the pancreas from a dog the blood-sugar rises and glycosuria develops Later the urinary excretion of nitrogen rises and ketonuria develops, indicating that the rate at which protein and fat are being broken down is accelerated.[72] If now the anterior-pituitary gland is removed, the excretion of urinary nitrogen and the ketonuria diminish, and at the same time the blood-sugar level falls and glycosuria decreases[72 73] Hypophysectomy has impaired the ability of the liver to form sugar from non-carbohydrate materials and to maintain the blood-sugar at the high level characteristic of diabetes.

In these two conditions, phloridzin poisoning and pancreatectomy, the liver is secreting sugar into the

blood at an excessive rate, and the question arises as to the effect of hypophysectomy on the liver when it is secreting sugar at normal rates What part does the anterior pituitary gland play in determining the supply of sugar to the blood in normal circumstances? After removal of the hypophysis from a normal animal there is a pronounced tendency for the blood-sugar level to fall on fasting, and not uncommonly such animals die from hypoglycæmia [22 26] Cope has shown that this fall of blood sugar does not take place before the glycogen content of the liver is greatly reduced, and that after death glycogen is present in the liver only in traces [22] This abnormal reduction of liver glycogen by fasting can be attributed to the impaired ability of the liver to manufacture sugar from non carbohydrate sources and thus replenish its store of glycogen The hypoglycæmia exhibited by the fasting hypophysectomised animal demonstrates that in the absence of the pituitary gland the liver cannot maintain the normal supply of sugar to the blood, and in this connexion the evidence that after removal of the anterior pituitary gland the glycogen in the liver is resistant to mobilisation as sugar is important [23] Further proof is, however, required on this point It appears, therefore, that removal of the anterior pituitary gland impairs the hepatic mechanism concerned with the maintenance of the appropriate head of pressure of sugar in the blood and reduces the ability of the liver to manufacture sugar from non carbohydrate materials

These functions of the liver can be restored to full activity in hypophysectomised animals, and stimulated to excessive activity in normal animals, by injection of extracts of the anterior pituitary gland When such an extract is injected into the hypophysectomised animal, the tendency for the blood-sugar to fall spontaneously disappears When the extract is injected into a hypophysectomised depancreatised dog, the amelioration of the diabetes, consequent upon hypophysectomy, is removed Hyperglycæmia and glycosuria become severe, the excretion of urinary nitrogen rises, and ketonuria develops [72 73 117] Formation of sugar from non carbohydrate sources has again been raised to the excessive rate prevailing in the ordinary depancreatised dog Similar effects are produced even in the normal animal After injection of the extract hyperglycæmia, glycosuria, and ketonuria appear, but in the normal animal, for some reason that is not yet understood, the excretion of urinary nitrogen does not increase For the manifestation of these effects the liver is essential [73] It has been suggested by Cope and Marks [23] that anterior pituitary extracts also facilitate the mobilisation of liver glycogen Their suggestion was based on the observation that the hyperglycæmia following subcutaneous injection of adrenaline was increased in animals treated with these extracts This suggestion has recently been criticised because it has since been found that the hyperglycæmia after intravenous injection of adrenaline is not increased [110 141] But the facts that after injection of the extracts slight external stimuli readily produce hyperglycæmia,[23 142] and that in partially hepatectomised animals treated with these extracts a fall in blood sugar leads to an excessive outflow of sugar from the liver,[69] both point to the increased facility with which the liver supplies sugar to the blood in these circumstances Whatever the decision on this point, however, it appears that extracts of the anterior pituitary gland accelerate the formation of sugar by the liver from non carbohydrate sources and facilitate the hepatic mechanism concerned with the maintenance of the blood sugar level (table III) It is thus clear that the anterior pituitary gland is of the utmost importance to the liver for its functions of manufacturing glucose from non carbohydrate sources and of supplying sugar to the blood at rates sufficient to maintain the appropriate head of blood sugar pressure

TABLE III—EFFECT OF ANTERIOR PITUITARY GLAND ON CARBOHYDRATE METABOLISM

Anterior-pituitary gland

Liver Facilitates	Peripheral Tissues Retards
(1) Formation of sugar from non-carbohydrate sources	(1) Insulin action on blood-sugar
(2) Breakdown of glycogen to blood sugar	(2) Muscle glycogen formation
	(3) Oxidation

In the foregoing considerations attention has been confined to the effects of the anterior-pituitary gland on the liver—i e, to the effects upon the production of sugar But the anterior-pituitary gland also influences the disposal of the blood-sugar, and the most striking example of this is its effect on insulin action [72 73 117] If insulin is injected into an animal which has previously been treated with extracts of the anterior-pituitary gland, it does not depress the blood sugar [25 139 141] This antagonisation of insulin action might be due to one of two causes either the extracts directly inhibit the action of insulin in accelerating the rate at which the peripheral tissues remove sugar from the blood, or they merely mask insulin action by promoting an excessive outpouring of sugar from the liver The former possibility has been proved to be correct Marks,[25] in 1936, showed that the effect of insulin in promoting formation of muscle glycogen in decapitated eviscerated preparations was greatly reduced if the animals had previously been treated with anterior-pituitary extracts, and later Himsworth and Scott [69] showed that these extracts also abolished the action of insulin in accelerating the fall of blood sugar in hepatectomised animals Factors are therefore present in the anterior-pituitary gland which reduce the action of insulin in the peripheral tissues

We have previously seen that the reduction in insulin sensitivity which follows restriction of dietary carbohydrate is a phenomenon localised in the periphery, and the question now arises as to whether the variations in sugar tolerance and in insulin sensitivity produced by dietary change are referable to changes in the activity of the anterior pituitary gland McNair Scott and I [69] investigated the effect of restriction of dietary carbohydrate on hypophysectomised rabbits and found that the normal effect of this measure in impairing sugar tolerance and insulin sensitivity was greatly reduced, if not entirely lacking We found further that injection of an extract of the anterior-pituitary gland into these animals resulted in an impairment of sugar tolerance and of sensitivity to insulin similar to that which develops in normal animals after starvation or restriction of dietary carbohydrate It therefore appears possible that the changes in insulin sensitivity and the correlated changes in sugar tolerance which result from dietary variations can be explained in part, if not entirely, by variations in the rate of secretion of a factor from the anterior pituitary gland

The association of impaired insulin sensitivity and diminution in the ability to oxidise glucose has been

emphasised previously, and it is therefore of interest that evidence has been produced indicating that the anterior-pituitary gland has an influence on the oxidation of glucose [72 73 117] When pituitary extracts are injected into normal animals, the respiratory metabolism becomes such as is usually taken to denote minimal combustion of carbohydrate.[43 101 116] In the depancreatised dog the respiratory metabolism is of this type, and administration of glucose to these animals does not produce the usual increase in respiratory quotient and oxygen consumption. If, however, the hypophysis is removed from a depancreatised dog, the respiratory metabolism now suggests that the ability to utilise carbohydrate has been partially restored [13 74 120] The prolonged survival of hypophysectomised depancreatised dogs, in comparison with ordinary depancreatised dogs, is perhaps to be attributed as much to this restoration of their ability to use carbohydrate as to the fact that the production of ketones in these animals is insufficient to cause fatal ketosis.

One may well ask at this stage what function the anterior-pituitary gland subserves in the economy of the normal animal. The gland appears to be concerned with the reaction to deprivation of carbohydrate It seems that, when carbohydrate is restricted, the anterior-pituitary gland is stimulated to an increased secretion of its factors. By retarding oxidation of sugar and insulin action in the peripheral tissues it economises utilisation of the blood-sugar, and by facilitating increased production of sugar from non-carbohydrate sources in the liver it augments the amount available for maintaining the blood-sugar level (table III). When the restriction of utilisable carbohydrate is more severe than in simple starvation, as when through lack of insulin the body loses to a great degree its ability to use carbohydrate, these same reactions are called into intense activity, with the result that their manifestations dominate the clinical picture.

ADRENAL GLANDS

It is well established that the secretion of the adrenal medulla, adrenaline, plays a definite part in carbohydrate metabolism, and considerable evidence has recently been obtained which suggests that the adrenal cortex plays an even more important part. On injection of adrenaline in normal animals hyperglycæmia results,[15] and the degree of hyperglycæmia is roughly proportional to the dose.[36] This hyperglycæmia is associated with a depletion of liver-glycogen, and in hepatectomised animals adrenaline does not raise the blood-sugar.[91] From these facts it is concluded that adrenaline produces hyperglycæmia by mobilising liver-glycogen. When the blood-sugar is depressed by insulin, adrenaline is liberated,[19] and after hypoglycæmia the amount of glycogen in the liver is reduced [24] It therefore appears that in the emergency of hypoglycæmia adrenaline plays an important part in the return of the blood-sugar to normal levels Besides its central action in the liver adrenaline influences the abstraction of sugar from the blood by the peripheral tissues Cori [24] is of the opinion that adrenaline diminishes the peripheral utilisation of sugar, but by direct experiment Soskin et al.[124] have shown that the peripheral utilisation of sugar is not decreased, and recently evidence has been obtained which indicates that adrenaline increases the amount of sugar removed in the periphery.[70]

The rôle of the adrenal cortex in carbohydrate metabolism is still controversial. In the crises of Addison's disease and in the terminal days of survival of adrenalectomised animals hypoglycæmia develops [77 110] and the glycogen stored in liver and muscles falls to low levels [16] There appears to be some relationship between the adrenal cortex and the hypophysis. Viale [135] reported that pancreatic diabetes in the dog was ameliorated after adrenal ectomy, and Houssay and Biasotti [75] obtained the same results in toads Gondard [49] and Lewis and Turcatti [84] could not confirm this Using depancreatised cats, however, Long and Lukens [86] have consistently found that after removal of the adrenal glands the survival time of these animals is prolonged almost to the same extent as after hypophysectomy A similar disagreement exists about the effect of extracts of the anterior-pituitary gland on adrenal ectomised animals Houssay [73] and his colleagues state that adrenalectomy does not reduce the hyperglycæmia previously produced by such extracts in dogs, and that implantation of the pituitary gland into adrenalectomised toads still causes hyperglycæmia. McNair Scott and I have found that the glycotropic factor of the hypophysis is still active in adrenalectomised rabbits [69] On the other hand, Long [85] finds that in adrenalectomised and partially depancreatised rats extracts of the anterior-pituitary gland are without effect It is possible that these discrepancies may be explained as due to the differing reactions of different species of animals or possibly by differences in the extracts used.

THYROID GLAND

Glycosuria occasionally develops in thyrotoxicosis, and in such cases sugar tolerance is also impaired When the basal metabolic rate is reduced, either by administration of iodine or by thyroidectomy, the glycosuria diminishes or disappears and the sugar tolerance returns towards normal. Griffiths [52] reports that in cases of Graves's disease a high-grade insulin insensitivity, as judged by the insulin-glucose test, may be found, and that such insensitivity is diminished by thyroidectomy. After administration of large amounts of thyroid gland to rabbits the liver-glycogen practically disappears [28] and coincidentally the metabolic rate and the urinary excretion of nitrogen rise Usually the sugar tolerance in such animals is little impaired.[97] After thyroidectomy the return of the blood-sugar from hypoglycæmic levels to normal is said to be slow. Although it is possible that the secretion of the thyroid gland acts directly on the liver, such an assumption is not necessary. An alternative explanation of the events after administration of thyroid extract would be as follows. Thyroid extract raises the metabolic rate of the tissues and thus increases their demand for sugar The liver attempts to meet this demand first by liberation of glucose from glycogen and secondarily by increasing the rate of new formation of sugar from protein Such metabolic activity on the part of the liver can be produced by injection of extracts of the anterior-pituitary gland If the increased demand of the tissues for sugar in thyrotoxicosis causes the anterior-pituitary gland to secrete in excess the factor concerned in carbohydrate metabolism, the increased activity of the liver and the associated insulin insensitivity would be explained In this connexion the relative frequency with which diabetes develops in persons who have, or who have had, thyrotoxicosis [78] may be remembered when the production of permanent diabetes mellitus by administration of extracts of the anterior-pituitary gland is discussed

(To be continued)

PARENTERAL THERAPY WITH M. & B. 693 SOLUBLE

BY WILFRID F GAISFORD, M D Lond, M R C P

AND

G M EVANS, M D Birm, M R C P

PHYSICIANS TO DUDLEY ROAD HOSPITAL, BIRMINGHAM

AND

W WHITELAW, M B Glasg

PATHOLOGIST TO THE HOSPITAL

THE use of M & B 693 has materially reduced the case-mortality in pneumonia during the fifteen months since its introduction (Evans and Gaisford 1938, Anderson and Dowdeswell 1939, Agramat, Dreosti, and Ordman 1939, Flippin, Lockwood, Pepper, and Schwartz 1939, Graham, Warner, Dauphinee, and Dickson 1939, Meakins and Hanson 1939) This drug is still proving to be one of the least toxic of the sulphanilamide group, and no serious complications have followed its administration in more than a thousand cases at Dudley Road Hospital

The chief drawback is its liability to cause vomiting in some cases, though this seldom happens in infants and young children, in adults it may be a prominent feature The cause of the vomiting is not yet clearly understood, it may be of central origin or due to gastritis That gastritis plays some part in the process is suggested by the absence of vomiting in children, who are less subject than adults to gastritis Although the vomiting can be minimised by varying the mode of administration and dosage, so that it is seldom that insufficient drug is retained to produce the desired concentration in the blood, occasionally patients are encountered, especially the very ill ones, who are unable to swallow the tablets even when finely crushed and suspended This may be due to the general condition—e g, delirium—or to the state of the mouth In such cases parenteral administration becomes imperative In overwhelming or mass infections it may also be desirable to supplement the oral route with parenteral therapy It is particularly valuable in treating pneumococcal meningitis

From the earliest days of research on the anti pneumococcal properties of 2 sulphanilyl amino pyridine attention has been devoted to the possibility of producing a soluble form of the drug All substances examined have been rejected for a variety of reasons—e g, toxicity or lower therapeutic activity —with the possible exception of the sodium salt This, however, while possessing antipneumococcal properties had the serious drawback of being highly alkaline To overcome this difficulty an oily suspension (0 5 g in 2 5 c cm) of M & B 693 was prepared and widely used but did not prove altogether successful, because of the limited number of injections possible and the low concentration of the drug obtainable in the blood Owing to this unsatisfactory outcome attention was redirected to the possible clinical use of the sodium salt, which was first tried in a 25 per cent solution given intramuscularly (0 5 g in 2 c cm solvent) and subsequently in a concentration of 33⅓ per cent (1 g in 3 c cm) In the latter form it has been administered to many patients, and this communication presents our findings to date For the most part injections of 3 c cm have been given every three or four hours intramuscularly, but in a few cases the intravenous route has been employed, the solution being made up to 10 c cm with distilled water, however, the latter method led to vomiting and was followed by rigors in some cases The substitution of normal saline for distilled water as a diluent prevented the rigors, but, in view of the fact that intramuscular injection did not cause any such unpleasantness and was rarely followed by vomiting, it appears to be the method of choice for parenteral administration Despite the high alkalinity no untoward effects have followed the injections, and these have not been unduly painful Absorption and excretion are both rapid The effect on children has also been investigated, the doses employed varying from 0 15 to 1 0 g according to age, no ill effects being observed

Various pneumococcal infections have been treated successfully, but no attempt has been made to present the results in statistical form, since it was the therapeutic method that was being studied Specimen protocols are attached

INVESTIGATIONS UNDERTAKEN

At intervals after injection specimens of blood were taken and the concentration of M & B 693 was estimated Urine was similarly examined and, in four cases, vomitus and, in two cases, breast milk The number of investigations on each patient was determined by the degree of illness and by the hour of the day (or night), but samples of blood were taken to enable graphs to be plotted showing the concentration of the drug in the blood at approximately 15 minute intervals throughout the 4 hour periods Thus, one patient had samples withdrawn at ½, 1,

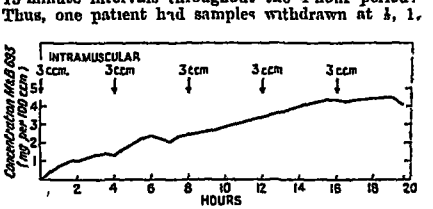

FIG 1—Concentration of M & B 693 in blood of patients given 1 g of M & B 693 soluble intramuscularly four hourly

1½, 2, 2½, 3, 3½, and 4 hours, another comparable one at ¼, ¾, 1¼, 1¾, 2¼, and so on, another at 5, 35, 65 minutes, and so on, for it was impracticable to collect samples of blood very frequently from the same patient A curve showing the average concentration of M. & B 693 in the blood of patients given intramuscular injections of 1 g of the sodium salt every four hours is shown in fig 1 It can be seen that an average concentration of 4 mg per 100 c cm is obtained after the fourth injection

Similarly, fig 2 shows the average concentration of M & B 693 in the blood after intravenous injection of 1 g every four hours By this method a concentration of approximately 4 mg per 100 c cm is obtained within half an hour The level then falls rapidly but rises again with subsequent injections

In most cases after initial doses of the sodium salt parenterally, 1 g of M & B 693 was given orally four hourly, and curves were obtained showing the maintenance of blood level by this means In fig 3 is shown the typical curve for a child (case 4) who received one intramuscular injection of 0 15 g and

four of 0 3 g. of the sodium salt at four-hourly intervals A concentration of about 4 mg per 100 c cm was reached after the fourth injection. Fig 4 is a curve showing the maintenance of the blood level by oral administration after several intramuscular injections had been given.

The blood levels varied within such wide limits in individual cases that it is impossible to present more

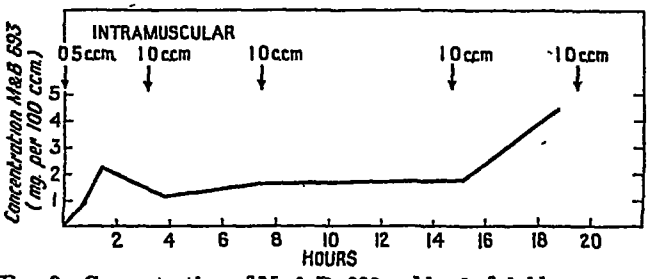

FIG 3—Concentration of M. & B 693 in blood of child given one intramuscular injection of 0·15 g M. & B. 693 soluble and four of 0 3 g. at four-hourly intervals

than average curves, but the investigations carried out show that the administration of M. & B. 693 soluble is a perfectly justifiable procedure

COMPLICATIONS

Three children developed small punched-out oval ulcers about ¼ in deep over the site of an injection, which had been given subcutaneously. Culture of the pus showed *Staphylococcus aureus* in one, and the other two were sterile That such a complication might occur is not surprising in view of the high pH and from animal experiments, but it has only happened in injections given subcutaneously in error, and these were in young children in whom intramuscular injection was difficult. It would appear, however, that the risk is slight, provided that the injections are given sufficiently deeply into the gluteal muscles, and that no drug is allowed to contaminate the needle-track. Further, it will seldom be found necessary to give more than four parenteral doses before oral therapy is initiated or resumed, owing to clinical improvement in the patient. Actually over 200 injections have been given without mishap

CLINICAL DETAILS

CASE 1.—A boy, aged 8, with right lower lobar pneumonia, admitted on the second day of illness,

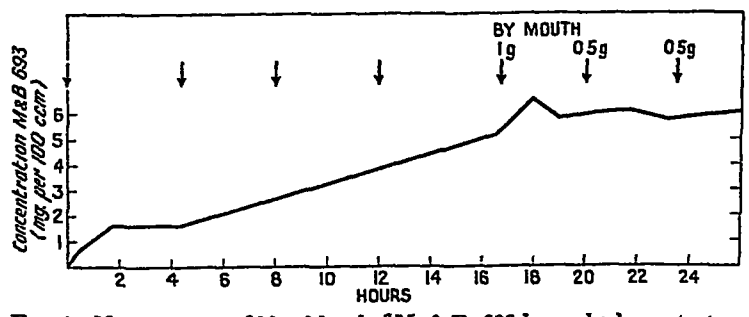

FIG 4—Maintenance of blood level of M. & B. 693 by oral administration after four intramuscular injections

received five intramuscular injections of 0 3 g. of M. &. B. 693 soluble at four-hourly intervals. One hour after the fifth dose the concentration of the drug in the blood was 4·8 mg. per 100 c.cm. The temperature fell in twenty-four hours after starting the treatment. Cured.

CASE 2.—A male infant, aged 11 months, admitted on the third day of bronchopneumonia, received four intramuscular injections of 0 15 g at four-hourly intervals. The temperature fell in twenty-four hours. Cured.

CASE 3.—A male infant, aged 16 months, admitted with extensive bronchopneumonia on the third day of illness, received five intramuscular injections of 1 c.cm. of the 25 per cent solution of the sodium salt at four-hourly intervals The temperature fell in twenty-four hours. Cured

CASE 4.—A boy, aged 6, admitted on the fourth day of a right lower lobar pneumonia, was given 0 15 g. of the sodium salt immediately and 0 3 g. every four hours for four injections by the intramuscular route. An hour and a half after the first injection the concentration of the drug was 2 2 mg. per 100 c.cm. of blood; at the time of the last injection it was 4 4 mg. per 100 c cm. The temperature fell in thirty-six hours. Cured.

CASE 5.—A youth, aged 16, with left lower lobar pneumonia, admitted on the fourth day of illness, received two injections of 1 g intravenously followed by 1 g. every four hours by mouth for five doses. A concentration in the blood of 1 8 mg. per 100 c cm. was reached an hour after the first injection. The temperature fell in fifty-six hours. Cured.

CASE 6.—A man, aged 25, with left lower lobar pneumonia, pneumococcus types XII and XIV being isolated, admitted on the fourth day of illness, was given five intramuscular injections of 1 g. at four-hourly intervals. Cured.

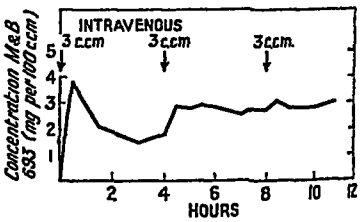

FIG 2—Concentration of M. & B. 693 in blood of patients given 1 g. of M. & B. 693 soluble intravenously four-hourly.

CASE 7.—A man, aged 29, admitted on the third day of a right lower lobar pneumonia due to pneumococcus type I, received four intramuscular injections of 1 g. of M. & B. 693 soluble at four-hourly intervals. Cured.

CASE 8.—A woman, aged 30, with left lower lobar pneumonia, admitted on the fifth day of illness. Pneumococcus type VII was isolated. Two intravenous injections of 1 g. were given at four hours' interval, followed by 1 g of M. & B. 693 orally every four hours for five doses. The patient was lactating, and two samples of breast-milk were examined for their content of M. & B. 693. Immediately after the second intravenous injection of the sodium salt the left and right breast-milk contained 2 5 mg. of the drug per 100 c cm. The concentration in the milk from the left breast rose to 3 mg. per 100 c cm. before the oral administration of the drug was started. An hour and a half after the fourth oral administration the concentration of the drug in the left breast-milk was 2 0 mg and in the right breast-milk 2 5 mg. per 100 c cm. The blood level half an hour after the second intravenous administration was 4 3 mg per 100 c cm. but reached 6 0 mg per 100 c cm. twenty-five hours after the last oral dose. The temperature fell within twenty-four hours after the institution of treatment. Cured.

CASE 9.—A woman, aged 76, very ill on admission on the third day of a right middle lobar pneumonia, was given 1 g. of M. & B. 693 soluble intramuscularly every four hours for seven injections. A concentration of 5 3 mg per 100 c.cm. in the blood was attained

one and three-quarter hours after the fourth injection The temperature fell in twenty-four hours Cured

CASE 10 —A woman aged 35 admitted extremely ill, on the sixth day of illness with both lower lobes consolidated, received seven intramuscular injections of 1 g at four-hourly intervals, followed by 1 g by mouth every four hours The temperature remained irregular for ten days and then fell Cured

CASE 11 —A woman aged 28, admitted on the fifth day of a right lower lobar pneumonia due to pneumococcus type III was given M & B 693 2 g by mouth every four hours for four doses An hour after the last dose the concentration of the drug in the blood was 3 4 mg per 100 c cm An intramuscular injection of 1 g of the sodium salt was then given, followed by another injection of the same amount after four hours, with two further injections at six-hourly intervals The concentration of the drug in the blood one and three quarter hours after the first injection was 7 3 mg per 100 c cm The patient vomited five hours after the second intramuscular injection The concentration of M & B 693 in the vomitus was 90 mg per 100 c cm The temperature fell within forty-eight hours after the start of treatment Cured

CASE 12 —A youth aged 16, with left lower lobar pneumonia of indefinite onset due to pneumococcus type XXIV There was also a tuberculous cavity at the left apex and the sputum was positive for tubercle bacilli The patient received two intramuscular injections of 1 g at four hours' interval The temperature fell within forty-eight hours Cure of the pneumonia

CASE 13 —A woman, aged 46 admitted on the fourth day of a left lower lobar pneumonia, received two intravenous injections of 1 g at four hours' interval A blood concentration of 1 6 mg per 100 c cm was reached seventeen minutes after the first injection The temperature fell within twenty-four hours Cured

CASE 14 —A woman, aged 44 with broncho-pneumonia, admitted on the fourth day of illness, received seven injections of 1 g of the sodium salt intramuscularly at four-hourly intervals Three hours after the last injection a concentration of 5 9 mg of M & B 693 per 100 c cm was found in the blood Eight hours after the injection the level was 4 7 and twenty-one hours later 3 3 mg per 100 c cm The temperature fell within twenty-four hours. Cured

CASE 15 —A man, aged 35, admitted on the second day of bronchopneumonia, was given M & B. 693 soluble intramuscularly in doses of 1 g every four hours for four injections, followed by M & B 693 1 g and then 0 5 g every four hours by mouth At the start of the oral administration the concentration of M & B 693 in the blood was 5 1 mg per 100 c cm The temperature fell within twenty-four hours Cured

CASE 16 —A youth aged 16, admitted with "influenza" which had been present for four days, was given intramuscular injections of 1 g at four-hourly intervals About two to four hours after the third injection he vomited, and the M & B 693 content of the vomitus was very high—180 mg per 100 c cm The patient's temperature fell within twenty-four hours of the start of treatment Cured

CASE 17 —A very frail senile man, aged 71, with pneumonia affecting the right lower lobe, admitted in a grave toxic state on the third day of illness, was given four intramuscular injections of 1 g at four-hourly intervals He died after three days, though the temperature fell within twenty-four hours of admission No post-mortem examination was made

CASE 18 —A woman aged 56 with chronic bronchitis and emphysema admitted with an acute attack of bronchitis of four days' duration, received intramuscular injections of 1 g of M & B 693 soluble at four-hourly intervals for five doses, followed by 1 g of M & B 693 orally A concentration of 1 g of M & B 693 per 100 c cm in the blood 0 4 mg of M & B 693 per 100 c cm in the blood was reached two hours after the fifth injection The temperature fell within twenty four hours Cured

CASE 19 —A man, aged 35, with right upper lobar pneumonia, admitted on the third day of illness Pneumococcus type I was isolated Five intramuscular injections of 1 g of the sodium salt were given at four hourly intervals, followed by 1 g of M & B 693 by mouth The concentration of M & B 693 in the blood two hours after the first administration was 7 5 mg per 100 c cm and rose to 10 3 mg per 100 c cm two and a half hours after the last injection The temperature fell within twenty-four hours Cured

CASE 20 —A youth, aged 16, with acute rheumatic fever, received four injections of 1 g intravenously at four-hourly intervals The concentration of M & B 693 in the blood half an hour after the first injection was 11 0 mg per 100 c cm , but after another hour this had fallen to 2 1 mg per 100 c cm , rising to 3 6 mg per 100 c cm after the second injection The patient vomited about two and a half hours after the second injection, the concentration of M & B 693 in the vomitus being 4 6 mg per 100 c cm

CASE 21 —A female infant, aged 1 year, with migratory right upper lobar pneumonia, was given five intramuscular injections of 0 15 g at four-hourly intervals The temperature fell, but it rose again a few days later, when a fresh area of consolidation appeared This second rise in temperature was controlled by M & B 693 by mouth A concentration of 7 2 mg of M & B 693 per 100 c cm of blood was obtained one and a half hours after the third injection Cured.

CASE 22 —A man, aged 52, admitted on the seventh day of a mild bronchopneumonia, was given four intramuscular injections of 1 g at four-hourly intervals The temperature fell within twenty-four hours Cured

CASE 23 —A man, aged 38, with left lower lobar pneumonia due to pneumococcus type I, admitted on the fourth day of illness, received two intravenous injections of 1 g at four hours' interval A concentration of 9 6 mg per 100 c cm was obtained one and a half hours after the first injection The temperature fell within forty-eight hours A clear sterile effusion subsequently developed, but was spontaneously absorbed Cured

CASE 24 —A man, aged 71, admitted on the third day of a type I right lower lobar pneumonia, was given two intravenous injections of 0 5 g of M & B 693 soluble at four hours' interval, followed by 1 g of M & B 693 every four hours by mouth An hour after the last injection the blood level of M & B 693 was 1 2 mg per 100 c cm A rigor occurred an hour after the second injection, when the blood level was about 1 5 mg per 100 c cm This patient developed a type I empyema but subsequently recovered

CASE 25 —A woman, aged 50, with well marked bronchopneumonia of indefinite onset, who was very ill on admission Type IX pneumococci were isolated from the sputum The dosage of the sodium salt was 1 g intramuscularly every four hours three injections being given Cured

CASE 26 —A man, aged 61, admitted on the second day of "influenza," received two intramuscular injections of 1 g at four hours' interval The temperature fell within forty-eight hours Cured

CASE 27 —A man, aged 25, admitted on the fourth day of a left lower lobar pneumonia Pneumococcus type XII was isolated Intramuscular injections of 1 g of M & B 693 soluble were given four-hourly for five doses, followed by 1 g of M & B 693 every four hours by mouth A concentration of 3 5 mg per 100 c cm was reached after the administration of the last dose Four hours after the last injection the patient vomited The vomitus contained 2 1 mg of the drug per 100 c.cm The temperature fell after four days Cured

CASE 28 —A man aged 29, admitted on the third day of a right lower lobar pneumonia due to pneumococcus type I, received four intramuscular injections of 1 g at four-hourly intervals The temperature fell within twenty four hours Cured

CASE 29.—A male infant, aged 1 year, admitted, very ill, on the seventh day of meningitis due to *Hæmophilus influenzæ*, was given six intramuscular injections of 0 15 g. at four-hourly intervals A concentration of 5 mg. per 100 c.cm. of blood was reached one and a half hours after the third injection. Died. *Post-mortem examination*: the child was a mongoloid; bilateral submaxillary abscesses containing *Staphylococcus aureus* were found. There was some pulmonary collapse and pleurisy (*H. influenzæ* and pneumococcus type III) Cultures of material from the middle ears also showed *H. influenzæ* and pneumococcus type III. Pus from the meninges grew *H. influenzæ*.

CASE 30.—A male infant, aged 7 months, very *ill on admission with severe bronchopneumonia*, was first treated with M. & B. 693 by mouth, 0 25 g. every four hours for five days, followed by 0 25 g. thrice daily for twenty-one days. Six intramuscular injections of 0 15 g. were then given at four-hourly intervals. The blood level was 6 7 mg. per 100 c.cm. five and a half hours after the last dose; after a further five and a half hours it had fallen to 4 4 mg. per 100 c.cm, and twenty-nine and a half hours after the dose the level was 2 0 mg. per 100 c.cm. Cured.

CASE 31.—A girl, aged 4, very ill with bronchopneumonia and pertussis, was given eight intramuscular injections of 0 3 g. and one of 0·6 g. at four-hourly intervals. Two hours after a dose of 0 3 g. the concentration of M. & B. 693 in the blood was 3 6 mg. per 100 c.cm. Five and three-quarter hours after an intramuscular injection of 0 6 g. the blood level was 5 0 mg. per 100 c.cm. Died. At post-mortem examination both lungs were found to be solid all over, with confluent bronchopneumonia.

CASE 32.—A male infant, aged 7 months, very ill with bronchopneumonia and pertussis, received twelve intramuscular injections of 0·15 g. at six-hourly intervals. Four and a half hours after the last dose the blood level was 5·2 mg. per 100 c cm. Died. At post-mortem examination severe bronchopneumonia was found, affecting both lower lobes. The hilar glands were enlarged. Pneumococci were found in both middle ears.

CASE 33.—A girl, aged 6, very ill with bronchopneumonia and pertussis, was given five intramuscular injections of 0 6 g. at six-hourly intervals. One and a quarter hours after the last injection the blood level was 12 3 mg. per 100 c cm.; forty-seven and a half hours later it had fallen to 0 2 mg. per 100 c.cm. Died. No post-mortem examination was made.

In four of the cases (11, 16, 20, and 27), in which vomiting took place, the concentration of the drug in the vomitus was estimated The values found were 30 mg, 180 mg, 4 mg, and 2 4 mg. per 100 c.cm

CONCLUSIONS

The occasional need for a parenteral form of administration of M. & B 693 is undoubted, and the sodium salt in a 33⅓ per cent solution (1 g in 3 c cm.) is an adequate preparation. Clinically it is no more toxic than M & B 693, is not unduly painful after injection, is rapidly absorbed and excreted, and is less likely to cause vomiting than M & B 693 given orally

In our experience intramuscular is preferable to intravenous injection, being easier for general use and less liable to cause reaction and vomiting, and giving an equally satisfactory concentration in the blood. It is essential that the injection be given *intramuscularly* and not subcutaneously, or non-absorption and local necrosis may take place Although comparatively few patients have been treated so *far, the results of this preliminary clinical trial* appear to justify its use in selected cases, either where there is a mass infection or in which M. & B. 693 causes persistent vomiting It is not intended to replace the oral preparation. A satisfactory scheme is to give four to six injections of 3 c cm. at four-hourly intervals These may be followed by smaller doses of M & B. 693 orally—e g, 1 g four-hourly till the temperature falls. Such a system is less likely to cause continued vomiting in susceptible patients than the large initial dosage in general use at present The drug may safely be given to children and babies in appropriately reduced dosage

We are indebted to Dr. T. M. Anderson, deputy medical superintendent, for permission to publish these cases; to our colleagues for their collaboration; and to Dr. W. R. Thrower for his help throughout the investigation. We are also indebted to Miss G. Phillips for technical assistance in the biochemical estimations. We have great pleasure in acknowledging the courtesy of Messrs. May and Baker Ltd., who provided us with supplies of the sodium salt.

Since this paper was prepared we have seen the article by E. K. Marshall and P. H. Long (*J. Amer. med. Ass.* 112, 1671) in which they state that the intravenous is the only satisfactory method of giving the sodium salt. This is at variance with our conclusions. Further experience may show that both methods will have their place in therapeutics.

PNEUMONIA COMPLICATING HÆMATEMESIS

TREATED WITH M & B SOLUBLE

BY ROBERT COOPE, B.Sc, M D Lpool, F.R C.P.
HON PHYSICIAN TO THE ROYAL LIVERPOOL UNITED HOSPITAL (LIVERPOOL ROYAL INFIRMARY), AND
E LEATHER, M B Lpool
HOUSE-PHYSICIAN AT THE HOSPITAL

THIS note reports a difficult clinical problem solved by the administration of the soluble sodium salt of M. & B 693 ("Dagenan sodium")

A man of 40 was admitted to the Liverpool Royal Infirmary with the history that on three occasions during the previous four days he had vomited a good deal of blood, following "a big feed of meat pies". For some time, and especially for the past six months, he had had pain after food and "indigestion", but he had not bothered much about it, nor had he seen fit to consult a doctor. Nine years ago he had been in the same hospital with right-sided lobar pneumonia.

It was only with difficulty that his own doctor persuaded him to go into hospital, in spite of the repeated vomitings of blood; but he was in poor condition on admission and thought he was going to die. He was very pale and markedly dehydrated, and his blood hæmoglobin, taken after his last hæmorrhage when the secondary dilution of his blood cannot have been complete, was only 40 per cent

With blood transfusions, and large amounts of glucose-salines given intravenously, he rallied reasonably well, despite further vomiting of a small amount of blood. The second day after admission, however, there was a sudden rise of temperature from the subnormal up to 101° F, and the respirations were 40 per minute. He had developed a little grunting cough, and complained of pain in the left side of the chest. Clinical examination made it clear that there must be a centrally placed patch of pneumonia in the left lung, and this was confirmed by the results of immediate radiography of the chest with a portable machine, and the coughing up of small quantities of sticky "rusty" sputum, infected with a mixed growth

of organisms Unfortunately, owing to an error, the pneumococci present were not typed Later the physical signs and X-ray appearances revealed a consolidation of the whole of the left upper lobe

The patient was now delirious, and the outlook seemed desperate Because of the hæmatemeses, the oral administration of drugs, and especially of tablets of M & B 693, was contra-indicated, for any recurrence of the vomiting or bleeding might be dangerous Happily we had by us a supply (through the courtesy of May and Baker Ltd) of the soluble salt, and the intramuscular injection of 3 c.cm of this was started as soon as the clinical diagnosis was made and was continued every four hours

During that night he was gravely ill, but next day his temperature had fallen to normal and he was much better He still needed much fluid, was he to have it intravenously or by mouth? We decided on the latter Over the following two days he made steady improvement, and as he was finding the intramuscular injection of the drug very painful—it is quite alkaline in reaction—it was discontinued The following day the temperature rose to 100° F and the drug was injected again every six hours until the temperature was normal again the next day Since then he has made a steady uneventful recovery, with resolution of the pneumonia, confirmed by X-ray He is now so far improved in his general condition as to be ready for gastro-intestinal radiography

Anyone faced with an emergency such as this must take action on clinical grounds It seemed clear that the hæmatemeses were due to bleeding from a peptic ulcer, and that it was therefore dangerous to treat a complicating pneumonia with tablets of the ordinary M & B 693 It was comforting to have available the soluble salt for parenteral injection The onset of pneumonia in a patient already gravely ill seemed to make the prognosis quite hopeless, and it was surprising and very pleasing to find that after all he did recover We have deliberately reported the case as it stands, for whether further investigations now confirm the presence of a peptic ulcer or not, they would not alter the clinical problem which had to be dealt with in those first few days after admission of the patient to hospital

PNEUMOCOCCAL MENINGITIS

A REVIEW OF 30 FATAL CASES AND A REPORT OF RECOVERY AFTER ADMINISTRATION OF M & B SOLUBLE

BY J VERNEY CABLE, M.D. N.Z., M.R.C.P. Lond.
ACTING RESIDENT PHYSICIAN TO THE DUDLEY ROAD HOSPITAL, BIRMINGHAM

PNEUMOCOCCAL meningitis is rare During the past three years 36,848 patients have been admitted to the general wards of the Dudley Road Hospital and only 30 of these were suffering from it There is no selection of cases at this hospital and no ill patient is refused admission The rarity of the condition is, however, offset by its fatality rate, which before the sulphonamide remedies were introduced was usually accepted as 100 per cent Cases of spontaneous recovery have been reported in America (Allman 1937, Frankmann and Stewart 1937), but there is no record of such an outcome at the Dudley Road Hospital and all the 30 cases to which I have referred were fatal

The age groups of the 30 patients are shown in table I It will be seen that 21 were under ten years of age and approximately two-thirds were under twenty Males numbered 28

Apart from its very high mortality, the disease is noteworthy for the speed with which it kills No patient admitted with pneumococcal meningitis

TABLE I—CASES GROUPED ACCORDING TO AGE

Years—	Under 1	1–5	5–10	10–20	Over 20
Cases	9	7	7	3	13

survived a week in hospital, and 26 of the 30 were dead within three days The diagnosis was confirmed in all cases by lumbar puncture and bacteriological examinations or by autopsy The post-mortem findings in the 19 cases examined are set out in table II It will be seen that bronchopneumonia, lobar pneumonia and otitis media were the common accompaniments In one case no other pathological lesion was present, while in another the only other lesion was pulmonary tuberculosis (pneumococci present in large numbers in the meningeal exudate) In the case with ulcerative endocarditis, pneumococci were found in large numbers on the vegetations on the aortic valve, but the lungs were normal Of

TABLE II—OTHER PATHOLOGICAL CONDITIONS FOUND AT AUTOPSY

	Cases		Cases
Bronchopneumonia	4	Sinusitis (pneumococcal)	2
Bronchopneumonia and pneumococcal otitis media	2	Ulcerative endocarditis (pneumococcal)	1
Lobar pneumonia	4	Pulmonary tuberculosis	1
Otitis media (pneumococcal)	4	No other lesion found	1

the 4 patients with bronchopneumonia 3 were under a year old while all the 4 cases with lobar pneumonia were over twenty Of the 4 with otitis media alone 3 were infants, while those with both otitis media and bronchopneumonia were aged six months and six years respectively These findings are what one would expect, since otitis media and bronchopneumonia are common in the young, while lobar pneumonia is the usual pneumococcal disease of adults

A few cases of pneumococcal meningitis treated successfully with sulphanilamide and its derivatives have been reported, but the following is, I believe, the first reported successful case in which the new soluble sodium salt of 693 was used The preparation is put up in ampoules containing 1 gramme of the salt dissolved in 3 c.cm of fluid, and 1 g injected is stated to be equivalent to 2 g by mouth It is essential to give the injection deeply into the muscle and not into the subcutaneous tissue, or an abscess may result Estimations of the blood content of M & B 693 made at this hospital have shown that a high concentration can be quickly secured by intramuscular injection and maintained by four hourly injections (see chart)

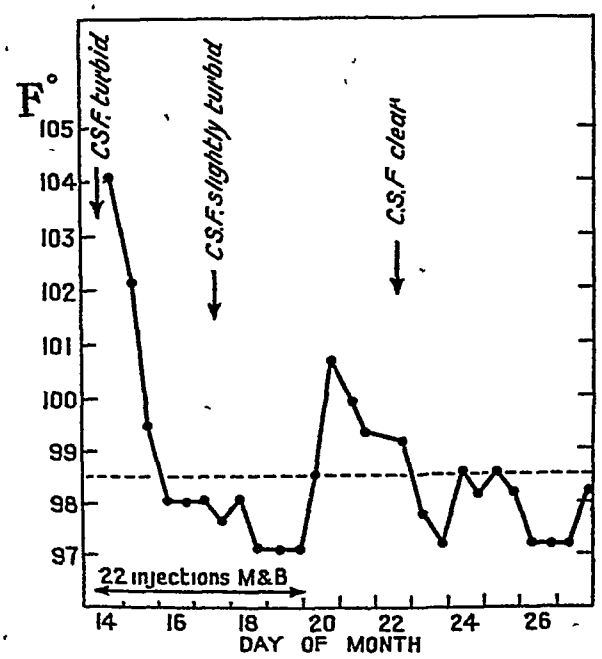
The patient was a girl of 7 admitted on the evening of April 11 with a history of vomiting and headache for three days She was very ill, pale, and slightly sallow, temperature 101°F, pulse rate 130 respirations 30 She was delirious and vomited continually, her neck was stiff, and Kernig's sign was positive Ears normal It was difficult to examine the chest because of the restless delirium, but no abnormal condition was found Lumbar puncture, thin turbid fluid under pressure Laboratory report on cerebrospinal fluid (C.S.F.) pus cells present pneumococci type x grown on culture

Intramuscular injections of M & B soluble (1 c.cm four hourly) were started at once Next day she was still delirious and vomiting, and required small

injections of morphine; but the temperature was falling. On the following day (April 16) it was normal, though there was no change in the general condition, and on the 17th she was still very ill with a threatening bedsore probably at the site of injection. Lumbar puncture produced a pale yellow fluid which looked almost clear but contained pus cells and yielded pneumococci on culture. By next day there was much less vomiting and the child was quieter, the temperature remaining down. On April 19 she vomited only once and showed interest in her surroundings. On the 20th, having now received a total of 22 injections of 1 c.cm., she was languid and weak, but there was no vomiting. On the other hand there was a slight rise in temperature.

On April 21 she was much better, asking for food and denying headache; no neck stiffness. M. & B. 693 by mouth was started, with 0·25 g. two-hourly. Next day she was vomiting again, though there was no headache or meningism. The C.S.F. was now a clear fluid (36 cells per c.mm., chiefly round cells); no organisms were seen in films and there was no growth on culture. The administration of M. & B. 693 by mouth was stopped because it was thought to be causing vomiting (total given 6·25 g.), and two intramuscular injections of M. & B. soluble, each of 3 c.cm., were given during the day. On April 23 the temperature was normal again, and after 0·5 g. of M. & B. 693 had been given by mouth in the morning no more was administered. On the 24th the child was well and very bright mentally. A small sterile abscess was present at the site of one of the injections, where apparently some of the solution was put into the subcutaneous fat. She has since remained well and seems in full health.

As spontaneous recoveries from this disease are on record it would be unwise to make considerable claims on the basis of a single case; but the temperature chart certainly shows rapid improvement after giving M. & B. soluble. The improvement in the child's general condition lagged behind the temperature fall by some two days; but this is what one might expect, for the meningeal exudate of pneumococcal meningitis is usually fairly copious and thick, and delirium, vomiting and meningism might continue until some of it had been absorbed. The second rise in temperature is probably attributable to the formation of the small aseptic abscess,



the occurrence of which shows the need to give the injections deeply into the muscle.

I am indebted to Dr. T. M. Anderson, deputy medical superintendent of the hospital, for permission to publish these cases; to my colleagues for access to their case-records; and to Dr. William Whitelaw for the pathological findings. My thanks are due to Messrs. May and Baker Ltd., who supplied the drug.

LITHOTOMY-TRENDELENBURG POSITION

FOR RESECTION OF RECTUM AND LOWER PELVIC COLON

BY O. V. LLOYD-DAVIES, M.S. Lond., F.R.C.S.

ASSISTANT SURGEON TO ST. MARK'S HOSPITAL, LONDON; SURGEON TO OUTPATIENTS, HAMPSTEAD GENERAL HOSPITAL

EVERYONE is familiar with the lithotomy and Trendelenburg positions, but I wish to point out some of the merits of using a combination of these two positions when operating on the rectum and lower colon. I have used this method for the past eighteen months and have had time to assess its advantages and eliminate some of its faults.

The aim has been to simplify operations on the pelvic portion of the bowel by placing the patient in such a position that a whole choice of procedures are available without moving or turning the patient once the operation has begun, for it to be possible to work either from the abdomen or the perineum, or alternatively, if there are two operators, for synchronous operating to take place.

I have attained this end by using special supports which are designed to hold the patient comfortably and effectively in this position (fig. 1). They are adjustable so that a patient of any size can be accommodated and, in addition, are designed to put the perineal tissues on the stretch when dissecting in that area, whilst this tension can be diminished when sewing up the perineum. Although my approach to this subject has been an individual one, both Kirschner and Devine have developed methods on similar lines.

It will be seen in figs. 2 and 3 that the abdominal and perineal exposures are a compromise. The best perineal exposure is obtained when the patient's thighs are well flexed and the best exposure of the abdomen when the thighs are extended. Excision of the rectum from the perineum in the lithotomy position will be a new departure for some surgeons, the majority of whom probably use the established left lateral position. This approach is, however, no new one, for it was described by Mayo in 1910 and is now used by many surgeons. Apart from slightly increased trouble in removing the coccyx I think it has every advantage over the left lateral position, since the tissue planes are held more on tension and the left and right sides are exposed equally well.

Some considerable time has been given to developing the special props (supports) for the patient's legs to enable the ideal combined position to be obtained—i.e., the best exposure of both the abdomen and the perineum at the same time. As before mentioned, they are designed to fit any size of patient, the horizontal rod (H) and the vertical part (D) being extensible (see fig. 4). The props are set in the

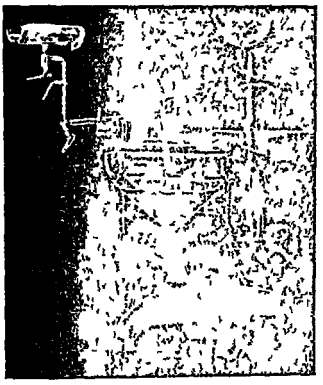

FIG 1—Supports attached to the table

ordinary *lithotomy* rod fixtures Upright A is marked off in inches so that both rods can be readily fixed at the same height, and as a general rule it is found that the horizontal bar (B) should be about five inches above the level of the table The upright (A) has one flattened surface to prevent the prop twisting round, and this flattened surface is cut in such a way that when fixed the horizontal part forms an angle with the edge of the table, giving a greater space between the two ball and socket joints (X), thus enabling the operator and assistant to sit comfortably opposite the perineum The upright (B) can be lengthened or shortened to accommodate any length of thigh and the ball-and-socket joint (X) allows for comfortable adjustment for the calf on the rest (W)

OPERATIVE PROCEDURE

The patient is placed in position after anæsthesia has been induced The legs are placed in the props and the calf rests are well padded with a triple layer of gamgee size 15 in by 12 in quilted and enclosed in a muslin pillow case with tapes for tying in position

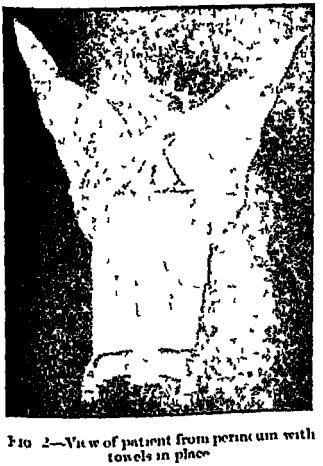

FIG 2—View of patient from perineum with towels in place

The various adjustments are made so that the best combined exposure of both the abdomen and the perineum is obtained The shoulders are supported by extended shoulder rests which are again well padded and take the weight from the acromio-clavicular joints and across the back of the shoulders by means of a narrow pillow The sacrum is lifted from the table by means of two sandbags Sizes 15 in by 5 in and 15 in by 12 in have been found to be satisfactory, and are used as shown in fig 5 The adjustment of the sandbags is important as their maximum lift should be at the greatest convexity of the sacrum—this will give a good exposure of the coccyx and also keep the pelvis in the best position If the sandbags are placed too near the lumbar region the pelvis will tilt away from the abdominal operator, and if they are too far down exposure of the coccyx becomes difficult For males, the penis and scrotum are kept out of the way by strapping them to the right thigh with adhesive tape Lastly, it is advisable to adjust the table in the Trendelenburg position before putting on the sterile towels, so that any downward slip on the part of the patient can be noted and readjustment made to prevent it

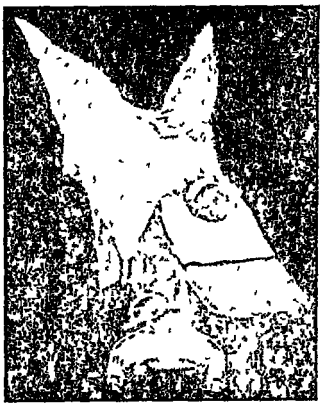

FIG 3—View of patient from the abdomen with towels in place

The arrangement of the patient soon becomes a simple matter which can be accomplished effectively in a few minutes When this has been done and the towels applied, no further alteration in the patient's position is necessary unless the operation turns out to be a completely abdominal one In this case by loosening the ball and socket joints X and Y on both sides the limbs can be extended and an almost full exposure of the abdomen obtained

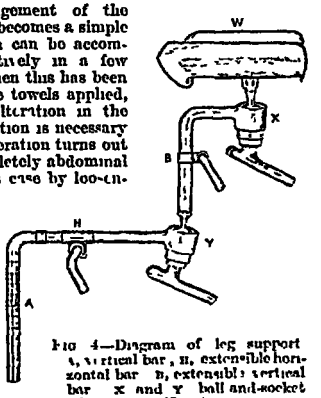

FIG 4—Diagram of leg support A, vertical bar, B, extensible horizontal bar H, extensible vertical bar X and Y ball and-socket joints, W, calf rest

With regard to towels, it should be noted that larger leggings than normal are required, and size 48 in by 54 in by 42 in have been found to be satisfactory

COMMENTS

The advantages of this method are considerable :—

(1) It allows a choice of procedures when the abdomen is opened and the growth is deemed operable An abdomino-perineal or perineo-abdominal excision can be performed with equal facility, and for growths at or above the recto-sigmoid junction a

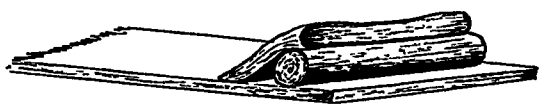

FIG 5—Arrangement of sandbags.

Hartmann's or Paul's operation may be done. The position is also ideal for an abdomino-anal excision with anastomosis and conservation of the sphincter.

(2) The time spent on the essentials of the operation of necessity remains unaltered, but unnecessary waste of time is avoided in the combined excisions—abdomino-perineal and perineo-abdominal—because the patient does not need to be turned This particularly applies to the perineo-abdominal operation in which there are two or three turns

(3) Shock is reduced by the shortening of operating time and the avoidance of turning the patient

(4) In abdomino-perineal operations the peritoneal floor can be closed over an empty pelvis

(5) It is possible to operate from the abdomen and perineum at the same time This requires two operators of experience and naturally results in considerable saving of time in straightforward cases Synchronous operating however is most important in cases in which the growth is particularly adherent, and I think that further developments on these lines will undoubtedly result in an increased operability-rate A number of these operations have now been done satisfactorily, and I propose to discuss this procedure more fully later

There are no serious disadvantages The position is admittedly a compromise, but for practical purposes an excellent exposure of both abdomen and perineum is in fact obtained. It must be realised that special supports are definitely necessary and attempts to use ordinary lithotomy crutches will lead to disappointment and will not give the method an adequate trial The removal of the coccyx, as before mentioned, may be slightly more difficult than when operating in the left lateral position, as its exposure is not quite so good This however is a minor point of little significance.

My thanks are due to Messrs. A. L. Hawkins and Co of New Cavendish Street, London, the manufacturers of the supports, and also to Mr. H. R. Bussey and Mr. V. L. Hardwick for the illustrations

INTERNATIONAL COURSE IN BALNEOLOGY.—An international postgraduate medical course in balneology is to be held in Budapest from Oct 2 to 8 Among those who will deliver lectures are Prof H. Vogt (Breslau), Prof. S. Graff (Hamburg), Geh. San.-Rat P Köhler (Bad Elster), Prof A. Slauck (Aix-la-Chapelle), Prof. F. Coste (Paris), Prof E Wybauw (Brussels), Prof E. Pisani (Montecatini), Prof. H Salvesen (Oslo), Prof. Ö N Holsti (Helsinki), Dozent E Folke Lindstedt (Stockholm) and Prof. M Neskovic (Belgrade) Further information may be had from the Central Committee for Postgraduate Education in Hungary, Eszterházy-utca 9, Budapest VIII.

LEUCO-ERYTHROBLASTIC ANÆMIA RESEMBLING ACHOLURIC JAUNDICE

BY H. C. LUCEY, M.D Lond., D.P.H.

PATHOLOGIST TO THE METROPOLITAN HOSPITAL, LONDON

A PORTER, aged 61, was sent to the Metropolitan Hospital from the outpatient department of another hospital, where several blood-counts had been done and lymphatic leukæmia diagnosed He said that his illness started with an attack of "influenza" five months previously, since when he had lost weight and become progressively paler and yellower.

CLINICAL RECORD

He had had no serious illness previously and no jaundice; nor was there any history of jaundice among his relations.

On admission he was obviously anæmic with a distinct icteric tinge. Temperature, pulse, and respiration normal. The spleen was enlarged 1½ in below the costal margin, and the liver was also slightly enlarged, ¾ in. below the costal margin. A small area of dullness was detected at the right apex behind

A *blood-count* gave the following results :—

Red cells	1,350,000	Polymorphs	67%
White cells	20,000	Lymphocytes	24%
Hæmoglobin	36%	Monocytes	3%
Colour-index	1·33	Eosinophils	2%
		Myelocytes and other immature forms	4%

The white-cell count at first appeared to be 35,000 per c.mm., but, on examination of a stained blood-film, numerous nucleated red cells were seen They numbered 75 per 100 white cells, and it was at once realised they had been included in the total white cell count (Nucleated red cells resist hæmolysis in acid distilled water, used for diluting and laking the blood, and appear in the hæmocytometer as small lymphocytes They are also liable to be mistaken for lymphocytes when a non-laking stain, such as Toison's fluid, is used for diluting both the red and white cells together) Therefore 75 out of the 175 cells in the hæmocytometer were nucleated red cells, and the true white-cell count was 35,000 minus 15,000 = 20,000 per c.mm It was doubtless due to the non-recognition of this snag that the original wrong diagnosis of lymphatic leukæmia was made, though examination of a blood-film should have put the observer right.

The nucleated cells were normoblasts, early and late erythroblasts, and an occasional megaloblast. The erythrocytes showed considerable anisocytosis, punctate basophilia, and polychromasia, but poikilocytosis was not a feature. Eve's halometer reading was 4·4, which corresponds to a modal mean diameter of 7·81 μ The anæmia was therefore macrocytic and hyperchromic. Reticulocytes reached the high figure of 45 per cent

Van den Bergh reaction—Direct reaction negative. Indirect reaction positive: bilirubin 2·5 mg. per 100 c.cm. (5 units).

Diagnosis.—On these findings a provisional diagnosis of pernicious anæmia was made and treatment with liver and iron started. True, a leucocytosis of 20,000 per c.mm was against pernicious anæmia, but occasionally cases of this disease are met with, especially when there is a septic focus when the more usual leucopenia is replaced by a leucocytosis For confirmation a fractional test-meal was done. This, however, showed a normal acid curve.

The diagnosis of pernicious anæmia was therefore discarded and acholuric jaundice considered. A red-cell fragility test showed hæmolysis starting in 0·7 per cent. saline and complete in 0·45 per cent. saline. A normal control put up at the same time

showed the normal result—lysis starting in 0·45 per cent and complete in 0·3 per cent saline. Such an increase in the red cell fragility, taken in conjunction with the clinical signs—namely, jaundice associated with a positive indirect and negative direct van den Bergh reaction, enlarged spleen, and slightly enlarged liver—appeared to clinch the diagnosis of acholuric jaundice. Further, the leucocytosis with a few immature white cells, the large number of nucleated red cells, the high colour index, the high reticulocyte-count, and the absence of poikilocytosis were all in favour of this diagnosis. It might be objected that the red blood cells were not the typical small globular cells found in this disease, but in a crisis "in adults particularly there may be a marked macrocytosis rather than the characteristic apparent microcytosis, this occurs especially when the count is low" (Whitby and Britton, 1937).

Course of illness.—A second blood-count, done eleven days after admission, showed a distinct worsening of the condition. The hæmoglobin had fallen to 26 per cent and the red cells to 900,000 per c.mm. Colour index 1·14. The nucleated red cells now exceeded the white cells in the proportion of 125 to 100. The false total white cell count was 45,000 per c.mm. and the true count 45,000 minus 25,000 = 20,000 per c.mm.

A blood transfusion (450 c.cm.) given at this stage had a striking effect. The hæmoglobin and red cells rose steadily, while the nucleated red cells and other abnormal forms fell rapidly. The patient's complexion changed from a lemon-yellow to a rosy pink. His weight increased slightly and his general condition steadily improved, so that in a few weeks he was allowed to get up. Liver and iron were still being given.

In the 11th week the red cells showed the same high degree of fragility as on admission, but the nucleated forms had now disappeared.

In the 20th week the reticulocyte count was 1·6 per cent. The accompanying chart shows the red cells about this period increasing at a greater rate than the hæmoglobin, so that the two curves cross. After this the colour-index remains less than unity. Stained films made about this time showed the red cells to be uniform in size and shape and rather small. There were no abnormal forms. Several haloometer observations gave an average reading of 5, which corresponds to a modal mean diameter of 6·88 μ. The blood picture had in fact changed from macrocytic and hyperchromic to microcytic and slightly hypochromic.

Revision of diagnosis.—At this stage the question of splenectomy was being considered, when the illness took a sudden and dramatic turn. Œdema of the right arm and upper part of the right chest set in. This focused attention on the small area of dullness which, on admission, had been noted at the apex of the right lung, and it was found to have increased both in extent and intensity. A radiogram showed a dense area of opacity in this zone. Besides this development, palpation of the right side of the neck revealed some slightly enlarged lymph-glands. Carcinoma of the lung, with lymphatic spread to the right arm and chest and to the cervical glands, had now to be considered. A cervical gland was removed, and section showed it to be infiltrated with carcinoma. The histological picture was peculiar, owing to the relatively large amount of clear or foamy cytoplasm, due to fatty degeneration, possessed by the anaplastic cancer cells. So again the diagnosis had to be altered. This time it was changed to primary carcinoma of the lung with leuco-erythroblastic anæmia.

This type of anæmia, when due to carcinoma, is always associated with secondary deposits in the bone marrow, which is stimulated to turn out both white and red immature cells. Radiograms at this stage, however, failed to reveal any deposits. (They were found post mortem.)

Terminal phase.—Iron and liver were now stopped, but in spite of this and the spread of the cancer, the blood, curiously enough, continued to improve, and by the 25th week the red cells had reached the 5 million mark. A fragility test done at this stage showed lysis starting in 0·5 per cent saline—a decided approach to normal. Thereafter, though his physical condition began to deteriorate, the patient developed a troublesome cough, his appetite failed, and he lost weight, his red cells and hæmoglobin dropped only slightly. A leucocytosis persisted throughout the illness. His temperature on the whole kept pretty steady, with only occasional rises to 99° or 100° F. Death took place in the 36th week after admission.

FINDINGS

Post-mortem.—Only those tissues and organs showing pathological changes are here described.

Lungs.—The whole of the upper lobe of the right lung was solid and so firmly adherent to the chest wall that it could not be removed without leaving portions behind. Microscopical section showed an anaplastic carcinoma which had arisen in an old tuberculous focus. A solid nodule, the size of a small walnut, was found in the upper lobe of the left lung. This at first was thought to be a secondary growth, but microscopical section proved it to be an active tuberculous focus. A *lymph-gland* removed from the bifurcation of the bronchi showed, on section, a combination of miliary tubercles and infiltration with secondary carcinoma, the cells of which were anaplastic and fatty like those found in the cervical lymph-gland.

The *liver* was enlarged and studded with secondary deposits. Microscopical section showed the carcinoma cells to be less anaplastic and less fatty than in the lung and lymph-glands. These were in solid columns with, here and there, incipient acinous formation. Free iron was present. The *spleen* was also enlarged (weight 12 oz.), free iron was present in abundance. Both *adrenals* were enlarged, with secondary carcinomatous deposits. An *abdominal lymph-gland* proved to be infiltrated with growth. Here the carcinoma cells were of two types

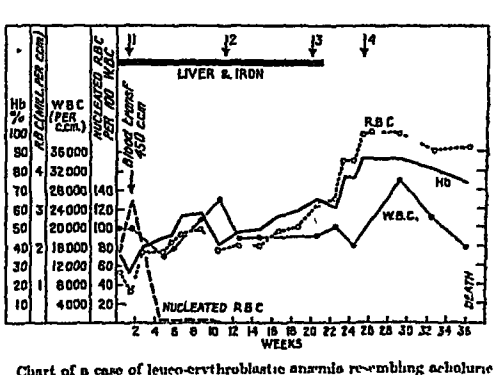

Chart of a case of leuco-erythroblastic anæmia resembling acholuric jaundice. Hb, hæmoglobin; R.B.C, red blood corpuscles; W.B.C, white blood corpuscles. Arrow 1: reticulocytes 45 per cent; hæmolysis in fragility test starts in 0·7 per cent saline. Arrow 2: hæmolysis starts in 0·7 per cent saline. Arrow 3: reticulocytes, 1·6 per cent. Arrow 4: hæmolysis starts in 0·5 per cent saline.

the fatty anaplastic variety already described and deeper-staining cells in acinous formation.

Humerus.—The left humerus was removed and sawn through its whole length. The marrow was obviously hyperplastic throughout, of a deep red-purple colour containing a few small pale patches. A microscopical section of one of these pale patches showed large, fatty, and lightly stained carcinoma cells, identical with those found in the lung and lymph-glands

Right axillary fold.—Since the tissues in this region were so much hardened and thickened, a microscopical section was made to determine if carcinomatous involvement of the lymphatics, as a direct spread from the lung adherent to the chest wall, had taken place. This was plainly shown to be the case, and was the cause of the solid œdema of the right arm and chest.

DISCUSSION

Icterus gravis in the newborn and acute hæmolytic anæmia at any age, may both show a slight increase in red-cell fragility; but I can find no reference to any disease, other than acholuric jaundice, in which a considerable increase in red-cell fragility is described In acholuric jaundice it is the characteristic feature and commonly reaches 0·7 per cent saline. The chief interest in this case of proved leuco-erythroblastic anæmia associated with carcinomatosis lies in the fact that it resembled acholuric jaundice so closely, even to the high degree of fragility of the red cells Fragility tests done on two subsequent cases of leuco-erythroblastic anæmia, with carcinomatous deposits in the bones but no jaundice, gave normal results; but Vaughan and Harrison (1939) have found slightly increased red-cell fragility in two cases of leuco-erythroblastic anæmia associated with myelosclerosis. How far the associated tuberculosis affected the blood-picture in the case here described it is impossible to say As for carcinoma of the lung starting in an old tuberculous focus, that is well known; but I have no knowledge that the reverse process has ever been described. It appears that in this case the implantation of the carcinoma on the site of the old tuberculous focus awakened its activity The dense adhesion of the lung at this part to the chest wall was evidence of a lesion of long standing

It is possible that some cases of so-called acquired acholuric jaundice may really be unrecognised cases of leuco-erythroblastic anæmia At any rate this case shows the importance of excluding the latter disease by a thorough search of the body for a primary malignant growth and by radiography of the bones for secondary deposits, whenever a diagnosis of acholuric jaundice, largely based on increased red cell fragility, is unsupported by a history of previous attacks of jaundice in either the patient or his relations It was fortunate that this case revealed its true nature before splenectomy was performed

My thanks are due to Dr. Norman Hill for permission to use the clinical notes of his patient.

MEDICAL SOCIETIES

NATIONAL ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS

AT the twenty-fifth annual conference of this association, held in Belfast from June 29 to July 1, with the Marchioness of TITCHFIELD, the president, in the chair, a discussion on the

General Administration of Tuberculosis Schemes

was opened by Alderman E. H. RICKARDS, J.P., who divided the administration of a tuberculosis scheme into four sections (1) Discovery and diagnosis: there were, he thought, still too many people in whom the early stages of the disease remained undetected owing to the difficulty of persuading some people to submit to examination and owing to the lack of propaganda whereby general practitioners might be made acquainted with the existing facilities (2) Treatment: there were few administrative difficulties here except insufficient accommodation to meet the long waiting-list of some authorities (3) Isolation and prevention: much success had followed the use of shelters and separate sleeping accommodation, education in hygiene, and rehousing schemes. (4) Care and aftercare of the patient and his family: the funds of care committees could not rise to every type of assistance necessary, and difficulty was often met in the case of the young bread-winner discharged from sanatorium as fit for "light work," because light work was almost unobtainable So far no serious effort had been made to find suitable work for these patients, and he suggested the setting up of workshops in connexion with a sanatorium at which discharged patients could be profitably employed for regulated hours.

Dr ANDREW TRIMBLE said that any such scheme must concern itself both with the care and cure of the patient and with the prevention of a further spread of the disease, for the decline in mortality was due more to the limitation of infection than to cures He outlined the development and progress of anti-tuberculosis measures in Belfast (where the death-rate had dropped by 67 per cent. from 1914 to 1938), put in a plea for a periodic review of any scheme, and suggested certain lines along which fresh endeavour might be directed, such as a study of the whole individual as a social unit, the cultivation of the health habit, and the training of school teachers in recognising suspicious signs of oncoming disease

Dr. W L YELL looked upon the tuberculosis dispensary as the foundation of all schemes, hence the choice of a tuberculosis officer and nurse were of prime importance He maintained that patients with early pulmonary, bone, or joint tuberculosis and those in an advanced stage of pulmonary disease should be given prior claim to institutional treatment, the intermediate group being best catered for by the colony system, which should be more generously subsidised. Dr Yell then referred to the success of a small maternity unit at one of the Essex sanatoria to which patients are admitted six weeks before term and retained for three to six months after delivery. This, it was hoped, would banish many of the dangers attached to parturition in tuberculous women

Dr P W EDWARDS, in a paper on

Arrangements for Artificial Pneumothorax

said that, before an artificial pneumothorax was induced, the operators should make sure that there were adequate facilities for carrying on the treatment These facilities he divided into "essential" and

"desirable" The former included an experienced physician, a thoracic surgeon, an X ray equipment for screening and taking pictures, and a suction apparatus for trocar and cannula The "desirable" facilities included a rapid gas replacement apparatus, an operating theatre for internal pneumolysis and phrenicectomy, and a quick method for sterilising needles in bulk

Dr B R CLARKE computed that 50 per cent of all patients with open pulmonary tuberculosis required a pneumothorax He regarded the induction as often a matter of urgency and deplored the lengthy wait for accommodation that was often encountered He emphasised the need for experience in spacing refills and preferred frequent small refills controlled by screening Since the main object of a pneumothorax was to bring about the lasting cure of the patient, the mental and physical reaction of the patient to the treatment should be constantly studied

Dr BRENDAN O'BRIEN considered the control of carriers to be the most important point in the prevention of tuberculosis, and this could be effected only by early diagnosis and adequate treatment There was a tendency to use the artificial pneumothorax as a substitute for sanatorium treatment, whereas they should be complementary, and he was opposed to inducing a pneumothorax without a preliminary period of observation

In the discussion that ensued Dr GEORGE DAY hoped that tuberculosis officers and others with charge of pneumothorax patients would be provided with facilities for screening and radiography This was not universal at the present time, with the result that the lung was either too much collapsed or there was a risk of the pneumothorax being lost

On the second day, with Sir PERCIVAL HORTON-SMITH HARTLEY in the chair, Dr GEORGE JESSEL, opening a discussion on

Tuberculosis in the Adolescent

said that the adolescent and young adult population had not participated in the continuous decline in the tuberculosis death rate from 1901 to 1909, but that from 1933 onwards a steady fall had been noticed After mentioning the possible predisposing factors that had been investigated by other workers, such as shortage of food, fatigue, work, and worry, he concluded that, apart from shortage of food, which the Registrar General thought significant in explaining certain periods of arrested fall, no single factor was responsible With regard to treatment the outlook had become more favourable, but treatment must be applied early Rest was the most important item, and artificial pneumothorax was useful in suitable cases On the preventive side the examination of contacts should be compulsory and universal. One examination was not enough, they should be kept under observation for at least five years

Dr F S HAWKINS cited the figures for Wales as showing the highest incidence of the disease to be in the adolescent age group, and to account for this he invoked poor housing and poor food, the anxiety of finding a job, and the struggle to retain it Certain symptoms should be regarded as danger signals, such as a constant succession of colds, aphonia, lassitude, a failure to gain weight, and amenorrhœa Treatment should be prompt and prognosis guarded, especially in young women, and an annual radiographic examination of all persons between 14 and 21 was desirable if prevention was to be ensured

Dr D S PRICE said that the primary infection of childhood should not be regarded as benign, for it might progress to more serious manifestations There were now more tuberculin negative adolescents in the community than thirty years ago, and as a result more people were becoming infected for the first time relatively late in life In Eire, for example, only 11 per cent of healthy girls of 14 in the country gave a positive reaction She thought there was a connexion between this and the high death rate in the 15–25 age group, and she asked for more consideration to be given to the negative reactor

Mr A R FOSTER, headmaster of the Belfast Royal Academy, attacked the present day system of education as fostering the spirit of mental cruelty. He illustrated his points by recounting a day in the life of an average pupil aged 16, in which the child was compelled, by his teachers during the day and his parents in the evening, to expend a sum total of physical and mental energy that would make the day's work of a coal heaver "look like a pleasant afternoon in the garden" He preferred quality rather than quantity in academic learning and thought that these deficiencies in our educational system were predisposing factors to tuberculosis.

Alderman P ASTINS, J P, drew attention to numerous gaps in the present legislative framework and the need for amending such legislation so as to make the local authorities responsible for many social activities now only permissive He laid particular emphasis on the need for adequate rehabilitation of a patient when he left sanatorium, and he suggested that the state could profitably reserve a proportion of its lighter jobs for such people, as indeed it did already for the disabled ex Service man.

Dr W M MACPHAIL gave an account of the occupational training at Burrow Hill Sanatorium colony Unfortunately there was not time for details, but he said that about a third of the patients stayed at the colony the full length of time and these had little difficulty in finding suitable employment in after life

Dr LLOYD RUSBY distinguished between the tuberculous and the catarrhal [illegible] in a contact community and suggested that [illegible] research should in future be devoted to a study of the constitutional factor with the object of early recognition of susceptibility rather than the established disease

Dr BANSZKY described the [illegible] technique of photographing the fluoroscopic image This had a bearing on the question of mass radiography for a permanent record could be obtained for a film

Dr J B MCDOUGALL [illegible] discussion on

Architecture [illegible]

from the points of view of [illegible] who was satisfied if a [illegible] of the patient, [illegible] and recreative [illegible] as his temperament [illegible] whose main [illegible] brief for the [illegible] an enormous [illegible] cited the [illegible] which [illegible] less than [illegible]

Mr [illegible] also [illegible] and [illegible] in [illegible] favour [illegible]

compactness, with administrative and clerical services centralised and the patients confined to the ground floor He condemned the use of radiators as heating by convection and preferred the radiant type of ceiling heating with steel pipes through which hot water could be passed

Dr. BLYTH BROOKE said that a tuberculosis dispensary both externally and internally should be one to inspire confidence and create a friendly and homely atmosphere He outlined the details of lay-out and illustrated his points with a plan of the Finsbury health centre

Dr E. K. PRITCHARD, with experience of the new health services at Southwark, said that he was not in favour of conditioned ventilation, because it required closed windows and it was sometimes difficult to convince the tuberculous patient that you were practising what you preached

Dr. F. R G HEAF thought well of Dr. McDougall's new hostel in view of the increased general demand for bed accommodation, and Mr. S. LOUTIT said that the designing of a tuberculosis institution should be the job of an outside architect and not of a borough surveyor.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY

AT a meeting of this society in Newcastle-on-Tyne on May 10 Prof. E. FARQUHAR MURRAY, the president, delivered his presidential address, entitled

Retrospect, Introspect, and Prospect

outlining the main changes in gynæcological practice which had taken place since 1911. Perhaps the most striking change was the development of a sound pathology which took regard of the whole patient. This was exemplified by the alteration in the treatment of retroversion and prolapse. In London in 1911 a third to a half of the laparotomies performed were for antefixing the uterus. As a conclusion to prolapse operations it was known to irreverent juniors as the "all red route" After such a training it was a relief to find that there were many backaches and very few retroverted uteri as a cause When he came to Newcastle in 1919 he found that ventrofixation had not been done for many years, although numerous papers were still being read advocating it To the Manchester school belongs much of the credit for establishing that a thorough plastic vaginal repair was sufficient to cure prolapse

During the same period there had been a swing of the pendulum from radical surgery to conservatism. Fortunately the clean pelvic sweeps preferred by those who considered a tidy pelvic basin as of prime importance were less common now. Years ago he had been told by a general practitioner that those who believed in removing ovaries should be made responsible for the patients' aftercare The replacement of hysterectomy by myomectomy in suitable cases was another instance of the same change in outlook On the other hand, much of the conservative surgery practised had been unsound—e g, the performance of salpingostomies without proof of any patency between the tube and the uterine cavity. Hormone therapy certainly was one of the main bulwarks of conservatism, but he wished there were a more satisfactory method of testing the preparations before the market was flooded at great expense to the hospitals

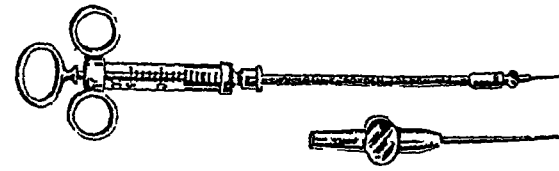
In obstetrics perhaps the most striking advance he had seen had been the almost complete disappearance of craniotomy and its replacement by cæsarean section Although the universal desire to provide anæsthesia for women in labour was commendable, under the present imperfect organisation of maternity services the idea that every midwife should have a powerful drug or apparatus at her disposal for every case was both dangerous and impracticable As a matter of fact the vast majority of women passed through labour without any analgesia at all and took no harm whatever By a judicious administration of the old-fashioned drugs it was possible to ensure a reasonably comfortable labour and a shorter and not intolerable second stage For most women nature was not so terribly unkind as she was made out

In the teaching of obstetrics one of the faults of the present system was the absence of a senior resident with the necessary standing in hospitals where junior residents were being taught their job. There was also a shortage of posts where men could learn postgraduate obstetrics. With the evolution of maternity services there would be an increased demand for general practitioners with such experience, and in some way this problem of instruction must be solved. The provision by most public-health authorities of a comprehensive consultant obstetric service was commendable, although some places had ignored the doctors and displaced them entirely in favour of whole-time officers Such a step had the most adverse effect.

NEW INVENTIONS

A SYRINGE FOR SIALOGRAPHY

IN several cases I have experienced difficulty with the usual syringes in injecting Lipiodol into the salivary ducts prior to sialography, and I have therefore designed the new type shown in the figure



This syringe, which is made by John Bell and Croyden, has rendered the technique of injection more precise and less irksome for both the patient and the operator.

HAMILTON BAILEY, F R.C S.

AN ELECTRIC UVIOMETER

Messrs. Henry Allday and Sons of 19, Warstone Lane, Birmingham, 18, have designed their new "A-T" uviometer on the principle of the photo-electric photographic exposure meter, the scale being calibrated directly in units of erythema dosage. The apparatus is easily portable, being some 5 in. long by 3½ in. wide and 2 in. deep. It is said to be sensitive to radiations of between 2800 and 4000 Angstrom units, the glass filter absorbing most of the radiations within the visible spectrum. If this is so it will register only the therapeutically valuable rays of a mercury-vapour lamp. It should be useful for comparing the emission of different sources of ultraviolet light or for estimating the deterioration of a lamp after long use. The uviometer costs 15 guineas.

REVIEWS AND NOTICES OF BOOKS

British Encyclopædia of Medical Practice

Vol XI By Various Authors Under the general editorship of Sir HUMPHRY ROLLESTON London Butterworth and Co 1939 Pp 730 35s

WITH the publication of this volume the editors—presumably with thankfulness—are nearing the end of their herculean task. Of the 36 articles the one by the editor in chief on the normal and pathological aspects of old age is worthy of special comment In a wise and sympathetic survey Sir Humphry Rolleston defines normal old age as "the process of inevitable involution which leads to normal death" Attempts at rejuvenation, whether by operative methods or hormonal therapy, are he thinks alike to be deplored Another important and succinct article is Dr John Rickman's on sexual behaviour and abnormalities Of the two methods of treating abnormalities, psycho analysis and suggestion, Dr Rickman thinks psycho analysis the more durable and on the whole the more satisfactory, in spite of its length and cost—much depending, it may be added, on the skill and integrity of the psycho analyst The immense potentialities of the new and fascinating knowledge about sex hormones are presented in a tripartite article in which Prof E C Dodds deals with their sources and constitution, Dr P M F Bishop with the therapy of menstrual and menopausal disorders, and Dr G L Foss with the use of male hormones

Sciatica is considered by Dr C W Buckley, who points out that the term is a loose one denoting merely pain in the distribution of the sciatic nerve whether due to a neuritis of the nerve trunk or of its components (root sciatica), or referred from an adjacent structure The various kinds of injection treatment are carefully described and Dr Buckley brings out the growing importance of orthopædic measures in refractory cases The accounts of injuries and diseases of the spine by Sir John Fraser and Mr J J Mason, and those of the spinal cord by Dr F M R Walshe, Mr Harvey Jackson and Dr J St C Elkington together occupy a hundred pages

The fact that involuntary sterility in marriage is often amenable to successful treatment, provided that both partners are willing to undergo thorough investigation, is not as yet fully appreciated either by the public or the profession Mr Eardley Holland explains the position clearly, but he is not always quite up to date. Dermatology is extremely well handled throughout the encyclopædia, and Dr Sydney Thomson's article on scleroderma and Dr Arthur Whitfield's on skin affections due to insects and acarines fully maintain the standard.

Like its predecessors this volume is profusely and beautifully illustrated

Shock and Related Capillary Phenomena

By VIRGIL H MOON, A.B., M.Sc., M.D., professor of pathology, Jefferson Medical College, Philadelphia, director of laboratories, Jefferson Medical College Hospital London Humphrey Milford, Oxford University Press 1938 Pp 112 21s

THERE has been no monograph on traumatic shock since Cannon published his book in 1923 and therefore the appearance of this work must attract attention, especially as Cannon himself contributes a short introduction The first eight chapters give a summary of the pathology and physiology of the capillaries, and in this part of the book the important contributions of Krogh and Lewis are well summarised There follows a brief account of the various theories of shock with special emphasis on the theory of traumatic toxæmia Most of the evidence in favour of this theory is already twenty years old and Prof Moon makes little mention of the mass of contrary evidence published in recent years He believes so firmly in traumatic toxæmia that he gives as his original contribution to the shock problem the post-mortem appearances of a fatal syndrome produced in dogs by implanting portions of striated muscle removed from other animals into the peritoneal cavity The remainder of the book is occupied by brief descriptions of such varied conditions as anaphylactic shock, heat stroke, diabetes, diphtheria, cholera, mercurial poisoning and intestinal obstruction The work is an excellent treatise in support of the theory of traumatic toxæmia, but the individual reader must decide how far it clarifies his ideas on shock and how far it increases his confusion

Essentials of Medical Electricity

(8th ed.) By ELKIN P CUMBERBATCH, B.M. Oxfd., F.R.C.P., D.M.R.E., medical officer in charge of electrical department and lecturer on medical electricity at St Bartholomew's Hospital, London London Henry Kimpton 1939 Pp 528 12s

IN this edition, which was published just before his death, Dr Cumberbatch has been able to include much new material without seriously increasing the size of the volume or its moderate price No book on the subject now contains less that is unnecessary or more that is of real importance to the average medical man In chapter 26, which forms an index of medical treatment, he will find a well balanced account of the general trend of electrotherapeutics as well as of its value in individual diseases Electrical testing is clearly described and the more obsolete methods have now been curtailed The various kinds of diathermy, the most interesting and probably the most important of the forms of electrical treatment, fill about a fifth of the book. The uses and dangers of surgical coagulation in malignant diseases are set out fully, but it is surprising that Dr Cumberbatch does not refer to the opinion held by many electrotherapists that malignant cells are especially susceptible to the action of heat and may therefore be destroyed at a temperature that is not high enough to coagulate normal tissues By the application of this principle some of the risks of surgical diathermy may be avoided.

The influence of the author's trip to America is evident and has sometimes led him to do less than justice to continental workers For instance, de Keating Hart published his paper on bipolar fulguration in 1907 It is difficult to see how this differs from electro desiccation, which Dr Cumberbatch says was devised in the United States by W L Clark, whose first paper was published in 1911 Dr Cumberbatch says that diathermy was first used in England by Dr F Nagel-chmidt in October, 1910 Actually it was used six months before on a patient of Sir Arbuthnot Lane's, and an account of this case was subsequently published. It is strange that there is no reference to the medical use of diathermy in trigeminal neuralgia But these are small points, and do not detract from the general excellence of the book.

The Relief of Pain

A Handbook of Modern Analgesia. (2nd ed.) By HAROLD BALME, M.D. Durh., F.R.C.S., D.P.H., formerly professor of surgery and dean of the school of medicine, Cheeloo University, China. London: J. and A. Churchill. 1939. Pp. 399. 12*s.* 6*d.*

IN this edition the author has included many new ideas and methods and a chapter by Miss Marjorie Houghton has been added on the nursing of pain. Dr. Balme ranges over the whole field of medicine, surgery, obstetrics, gynæcology, and the specialties, describing the clinical features and therapeutics of aches and pains big and little and from top to toe. Of necessity much of his material is compiled from the writings of others, untested by his own experience, but the compilation is concise as well as comprehensive, the main interest is strictly practical, and there is a large and well-arranged bibliography. The result is a useful and stimulating book, by an author most appropriately named.

China at War

By FREDA UTLEY. London: Faber and Faber. 1939. Pp. 306. 12*s.* 6*d.*

Miss Utley, whose thoughtful study of Japanese economic and military strength, published three years ago under the arresting title of "Japan's Feet of Clay," brought her into the front rank of writers on far-eastern problems, has just returned from China where she was one of the very few British newspaper correspondents in the war zone and the only Englishwoman to visit the Yangtse fronts. Her book provides a dramatic record of the effect of modern warfare upon the Chinese nation. We see, as on a screen, the result of air-raids on crowded cities; we hear the moaning of the women over dead and mutilated children; we watch the procession of homeless thousands, from villages deliberately destroyed by advancing armies or razed to the ground as part of the "scorched earth" policy; we note the philosophic patience and dauntless courage of the suffering peasants; and we wonder afresh what will be the outcome of this unequal struggle.

But although largely taken up with the political implications of the present conflict, Miss Utley's book is no mere political propaganda. It is a fine attempt to depict events as she saw them, and in her description of the field medical services she is unsparing in her criticism of the corruption, the inefficiency and the nepotism of the army medical corps. Lacking in the most rudimentary forms of equipment, deficient in trained personnel, and devoid of any adequate preparation for the transport and care of the wounded, the corps did little but provide bare board and lodging for such casualties as could secure a lift on an ammunition lorry, or could somehow drag themselves to the nearest military hospital. Her record is not, however, all painted in sombre colours, for she gives an account of the heroic efforts being made by the Chinese Red Cross, under the leadership of Dr. Robert Lim, to repair the terrible defects in the medical service. Encouraged and supported by General Chiang Kai-Shek and his gifted wife, and working in close harmony with Surgeon-General Loo Chi-teh, Dr. Lim has recruited a large number of well-qualified civilian doctors; he has established a fleet of mobile units, to operate between the field and the base hospitals; he has equipped a limited number of hospitals with expert staff and adequate supplies; and he has organised a system of intensive training for old army doctors, dressers, first-aid attendants, and hospital orderlies. In the carrying out of this effort he is appealing for practical assistance and no reader of Miss Utley's narrative could fail to sympathise with Dr. Lim's appeal.

Physiology of Muscular Activity

(2nd ed.) By EDWARD C. SCHNEIDER, M.P.E., Ph.D., D.Sc., professor of biology at Wesleyan University, Middletown, Connecticut. London: W. B. Saunders Co. 1939. Pp. 428. 14*s.*

THE physiological basis of muscular activity in so far as it has a bearing on physical fitness is now a question of national as well as of scientific importance. Accurate and up-to-date information will be found in this book, where in less than 500 pages a very complete account of the experimental and applied aspects of physical activity is presented. The first part is devoted to the functional contributions of the organs and systems concerned. The account of the physiology of muscular contraction has been revised in the light of modern knowledge but fortunately has not become too intricate. Muscle metabolism, the rôle of oxygen and respiration are explained lucidly, and the blood, heart and circulation receive due attention. Throughout these chapters there are innumerable practical examples in which the physiological reactions are given quantitative expression for specified types of exercise. The later chapters deal with the application of these principles to the problem of physical fitness. The effect of repeated exercise in promoting the improvement associated with "training" is fully discussed. The harmful effects of excessive or uncontrolled activity are considered in relation to fatigue and to staleness. A detailed account is given of various tests for physical fitness and this should be of great value to workers who have to examine recruits or candidates for work which demands a certain standard of fitness. Finally there are chapters on physical exertion under certain specified conditions such as in heavy industry, with varied external temperature, and at high altitudes. The book can be strongly recommended both for its scientific quality and its practical outlook.

Urology

(4th ed.) By DANIEL N. EISENDRATH, M.D., consulting urologist, American Hospital, Paris; and HARRY C. ROLNICK, M.D., attending urologist, Michael Reese, Mt. Sinai and Cook Co. Hospitals, Chicago. London: J. B. Lippincott Company. 1938. Pp. 1061. 42*s.*

SEVERAL important advances have been made in urology since the appearance of the third edition of this work four years ago, and these have necessitated a complete revision of the text. A large number of the illustrations that appeared in previous editions have been replaced, and new sections have been added on cystometry as a help to diagnosis in urinary dysfunction of the bladder, and on the diagnosis and operative treatment of adrenal hyperplasia and neoplasm. There are also new chapters on genito-urinary diseases in women and in children.

By concentrating attention on diagnosis and general lines of treatment, and by avoiding unnecessary descriptions of operative technique, the authors have succeeded in incorporating all this new matter without any considerable increase in the size of the volume. Their original aim has been kept in view—that of simplifying urology for teaching purposes—and, though it is one of the most complete, this is still one of the most readable works on the subject.

THE LANCET

LONDON SATURDAY JULY 8, 1939

STANDARDS OF FITNESS

GALSWORTHY divides human beings into two classes The first maintain that whatever is is right, the second that whatever is is wrong For a long time the second class have told us that we are a C3 nation, underfed and under exercised While admitting that the standardised death-rate fell during the last third of the nineteenth century from 21 to 17 per thousand, and during the first third of this century to about 13 per thousand, they say that it does not follow that the national stamina has improved to a corresponding degree In this they have the backing of the dietitians, who say that at least half the population—that half moreover who produce more than their share of children—do not get enough to eat They have also been able to quote the Army Council, who said "the present position (in 1935) is that if three men come forward to enlist one is rejected on sight, the second is rejected for physical, mental or educational reasons, and the third is finally approved" The medical examination of militiamen has, however, given them a severe setback Instead of the 66 per cent of rejections that they might have forecasted, of the first 50,000 men examined only 2 6 per cent were found to be unfit for any form of military service, 92 5 per cent were passed as fit to be called up for training, and the remaining 4 9 per cent as fit for the lighter jobs in wartime The politicians have lost no time in making capital out of these surprising findings "I should have thought," said Mr ERNEST BROWN, "that every member of the House, and everybody outside, would be proud of the fact that our social legislation within the last thirty years has given us these great results" But the triumphs of social legislation can hardly explain the discrepancy between the acceptances for the militia today and for the army only three years ago, and suggestions have been made in Parliament that the examination of the militia is inadequate and (provocatively) that "under any circumstances the men have got to be inside the armed forces"

The main reason for the discrepancy lies in the different standards of acceptance, and the effect of even seemingly minor alterations can be illustrated by the fall in rejections for the army that has followed changes in the last few years Up to 1936 recruits had to reach a definite standard of height, weight, chest-measurement, vision and dental condition, and to be free from certain minor physical defects, they had, in short, to be practically 100 per cent healthy in all respects On these standards, in the year 1935–36, 18 8 per cent of would-be recruits were rejected by army recruiters on educational or gross physical grounds without seeing the medical officer, and another 21 8 per cent on the medical examination In 1936 instructions were issued that recruits should not be rejected for minor physical defects that would not interfere with their duties, and since 1937 they have not been rejected on dental grounds In consequence the number of rejections by recruiters fell to 3 8 per cent and by the medical officers to 14 per cent in 1937–38 There are certain fallacies which make even these figures larger than they should be Some units have special requirements—for example the Guards, the gunners of the Royal Artillery, and the drivers of the Royal Engineers—and if a man applies for enlistment in one of these he may be rejected on medical grounds although he would be accepted for other units Further, an uncertain number of men who are rejected at one recruiting centre try their luck at others, so that they appear several times in the list of rejections

Taking the figures for last year, the total rejections for the army are only some 10 per cent greater than for the two active-service grades of the militia This difference might partly lie in the sources from which the recruits are drawn The militia are an almost entirely unselected sample of our men of 20 and 21 A large proportion come from comfortable homes and have been well fed during their adolescence Most recruits for the regular army have not had such advantages Many come from the homes of the unemployed and some have themselves been out of work for several years The importance of this factor has been demonstrated by the number of rejected recruits who have been raised to the required standard of weight, chest-measurement and even height at the two recruits' physical development depots In spite of the changes in the army requirements in the last few years, however, they are still sufficiently more exacting than those of the militia to account for a higher rate of rejections The army examination aims at determining whether a candidate is fit for the unit he applies to join, the militia examination whether he is fit to be a soldier at all There is, for example, no specified minimum of height, weight and chest-measurement for the militia, and some of the men with minor defects of feet or vision who are placed in grade 2 (a) of the militia would be rejected for the army. Thus those who draw conclusions as to improvements in the national physique by comparing the figures for the militia with those of the army, and especially those of the army several years ago, are deceiving themselves No one will deny that the health of our young men has turned out to be much better than expected, but we must look elsewhere for proof that it is much better than it was

AN ALTERNATIVE ROUTE

M. & B. 693 is twenty times less soluble in water than is sulphanilamide; for this reason it is absorbed more slowly and less completely from the alimentary tract. Actually the rate and degree of this absorption vary from patient to patient in a way which cannot yet be explained. These considerations, and the fact that coma or vomiting may render it difficult or futile to give the drug by mouth, make it desirable to find if possible some other method of administration by which an adequate concentration in the blood can be attained speedily and surely. The answer is the sodium salt, known here as M. & B. 693 Soluble, and more descriptively in the U S A as sodium sulfapyridine. Although several passing references to this compound have appeared in recent papers, the first full description of its use and action is contained in three papers which we publish this week and in another by MARSHALL and LONG [1] whose studies at Baltimore are evidently independent of the work going on in England and indeed have been conducted on different lines.

These authors, having satisfied themselves by a variety of toxicity tests in dogs and rabbits that the drug had a good expectation of proving safe, decided to give it to patients intravenously, taking the view that since a solution of sodium sulfapyridine is strongly alkaline this is the "only possible route" for injection. The solution used had a strength of 5 per cent. which is nearly isotonic and a pH of 10·7; the dose recommended is 0·06 g per kg. of body-weight and it is emphasised that the injection should be made at the rate of not more than 5 c cm. per minute. Studies of the subsequent concentrations in the blood suggest that diffusion into the tissues is nearly complete within ten minutes; the blood concentration is well maintained, scarcely falling at all during the first hour and to a varying extent, averaging a diminution to about two-thirds of the original maximum, in four hours Ten cases of pneumonia undergoing this treatment are briefly described, serving simply to show that it is feasible and apparently effective. The indications for the parenteral route are three incapacity to take sulfapyridine by the mouth, failure to attain an adequate blood concentration after administration by the mouth, and necessity for obtaining maximum effect as rapidly as possible. In severe cases it is evidently well to begin with an intravenous injection, thereby bringing the full action of the drug to bear within a few minutes, and to rely on oral administration for maintaining it. MARSHALL and LONG found it was rarely necessary to give more than two intravenous injections; sometimes even one might be enough. They have given sodium sulfapyridine intravenously to thirty patients in all, and observed no ill effects except that the injection sometimes caused vomiting. This vomiting, which occurred also in dogs, is of minor importance since it occasions no loss of the drug; it is of interest because it calls in question the current belief that the nausea and vomiting produced by oral administration are due to local action on the gastric mucosa.

Turning to the clinical trials in this country, Dr. CABLE records the successful treatment of a case of pneumococcal meningitis, while Drs COOPER and LEATHES were able to control pneumonia in a patient with a bleeding peptic ulcer—an exceptional (but strong) contra-indication to oral therapy. In both these cases the intramuscular route was used, and this was also the method adopted by Dr. GAISFORD and his colleagues in treating a considerable series of cases, 38 of which are briefly described A 33⅓ per cent. solution was used, 1 g. being therefore contained in the conveniently small volume of 3 c cm.; this is injected deeply into the gluteal muscles, where it causes little pain but may produce necrosis and abscess formation if any of the solution escapes into the subcutaneous tissues. The dose was repeated several times at intervals of four hours even in patients whose treatment was to be continued by the oral route GAISFORD and his colleagues have studied the rise in blood concentration during this form of treatment: the levels attained varied considerably, and the advantage of the intramuscular route appears to be rather the certainty of reaching an adequate (though often only moderate) concentration in the blood than rapidity in reaching it. They also tried the intravenous injection of diluted solution, but gave it up owing to the vomiting produced.

The direct conflict of opinion about the best route of administration seems to be a matter of balancing discomfort and disturbance—possibly to be mitigated by varying the intravenous technique—against the advantages of much more rapid effect and of fewer injections This form of treatment is evidently a useful advance and free from serious dangers, on the other hand it demands skill in the use of a needle and judgment in deciding when and how best to use it.

BOARDING-OUT

SCOTLAND has long been admired for the system there employed of boarding-out insane and defective persons in private families. During eighty years much experience has been gained so that the system works on the whole smoothly and effectively.[1] It is however emphasised in the twenty-fifth annual report of the General Board of Control for Scotland [2] that the selection of suitable cases, and to some extent of suitable guardians, requires close inquiry and local knowledge The public-assistance officer and district medical officer are immediately concerned in this, though the visits of a deputy commissioner of the board provide not only statutory inspection but the specialised and central supervision found by experience to be necessary for keeping up a general high standard of family care in widely varying districts and

2 Edinburgh H.M Stationery Office 1939 Pp 46 1s 6d

circumstances Defectives are apparently a more difficult problem than those sometimes bluntly described in the report as pauper lunatics The boarding of insane patients, it is said, does not provide the same difficulties as occur in the case of defectives In the case of the former, the majority suffer from some degree of dementia and are quiet, contented and well behaved The report remarks on the number of extremely disordered patients with paranoid tendencies who were apparently leading quiet peaceful lives in comfortable homes Many of the defectives boarded in urban areas presented a social or moral problem, often it had been the reluctance of the relatives to hand over a defective to the care of strangers which led to the patient remaining a slum dweller with nothing to occupy him but aimless wandering or standing at the street corner The defective placed under the care of well chosen guardians on a small farm or croft was much happier, sharing in the work and family life of those among whom he lived The high-grade defective has been found to be unsatisfactorily dealt with so long as there is inadequate provision of certified institutions and special schools, and where these defectives are under domiciliary care there is great need for them to have some communal interest and activity It is made clear in the report that many of the 1032 patients provided for in private houses at the beginning of 1939 had never been in any institution and that the term boarded-out is only loosely applicable The whole question of family care, as an alternative to institutional care, needs more attention in England than it has received The lessening of the financial burden upon the community is only one of its claims to consideration As the report of one of the deputy commissioners in Scotland indicates, it has been coming to the fore in the United States, the survey by H M POLLOCK[3] of the provision available in Europe has no doubt contributed to this awakening of interest, though in one or two states in America boarding out has been practised for a number of years

ANNOTATIONS

MEDICAL EMERGENCY IN CHINA

A FEW weeks ago Dr Harold Balme gave in our columns[1] some account of the effect of two years continuous warfare in China and set out to answer the question, foremost in people's minds here, how far the national medical services of China are in a position to cope with the present emergency The answer is partly given in a book which we review this week on another page Miss Ireda Utley, who has accompanied the armies on several fronts, tells of the inefficiency of the army medical corps and the heroic efforts of the Chinese Red Cross Under the leadership of Dr Robert Lim the Red Cross has organised a fleet of mobile units and is engaged in the intensive training of their personnel The League of Nations has responded to his appeal by the despatch of three commissions to organise effective measures to combat the serious outbreaks of epidemic disease, but what is now urgently needed is a model surgical unit to act as a teaching and reconstructive centre and to set a standard in the repair of injuries resulting from the war It is a hopeful sign of the times that the British Orthopaedic Association is willing to organise one of these centres as a mark of sympathy with the Chinese people, and to equip a teaching unit of 250 beds under the direction of an orthopaedic expert to be entitled "The Robert Jones Emergency Relief Surgeon" Members of the association have themselves generously subscribed a sum of £1100 towards the £3500 that would be immediately required The names appended to the letter on p 99 are sufficient guarantee of the practical wisdom likely to be shown in the disposition of the money Many people must have been deterred from contributing to the relief of suffering in China by the feeling that their quota would be negligible in face of the magnitude of the need But here is a direction in which something effective might be done with moderate means, and we commend the venture to our readers and through them to all who are alive to the welfare of China and what it may mean to posterity

CANCER RESEARCH IN YORKSHIRE

THE investigations[4] carried out in Leeds under the direction of Prof R D Passey and in Sheffield by Sir Edward and Lady Mellanby and also by Prof H N Green cover a wide field In Sheffield J W Orr and D E Price have studied the induction of primary cancer of the liver by an organic dye—butter yellow This substance produces first a cirrhosis of the liver, and the histological changes taking place during this process are being studied in detail An interesting observation is that another substance—carbon tetrachloride—also produces cirrhosis of the liver, but does not induce liver cancer The changes in the metabolism of liver cells during this process of carcinogenesis have been followed by Orr and L H Strickland An attempt has been made to determine whether carcinogenic substances are formed in a tissue (the skin) subjected to a physical carcinogenic agent (prolonged exposure to ultra-violet light) The skin was finely minced, dried and extracted by fat solvents The extract was then either applied to the skin for a prolonged period or injected subcutaneously No evidence of the presence of a fat soluble substance with carcinogenic properties was obtained Dr Clemmesen of Denmark, who has been working in the Leeds laboratory as a guest, had found in confirmation of previous workers that X radiation of the whole animal impaired an immunity to the transplantation of tumours A similar effect was produced by this procedure on the resistance to the Shope fibroma virus This virus induces in rabbits a transient tumour like proliferation of connective tissue If the virus was injected after a previous treatment with X rays the tumours which developed were larger and persisted longer, but eventually they regressed as they do in normal untreated rabbits The experiments were extended to the Shope papilloma virus This virus when rubbed into the skin produces extensive warty growths which sometimes develop into true malignant growths So far

4 Thirteenth annual report of the Yorkshire Council British Empire Campaign Park Square Leeds

irradiation of the whole animal has not produced effects for this virus analogous to those demonstrable for the fibroma virus

The work of the last few years has brought into prominence the importance of the inherited susceptibility to cancer as an ætiological factor. This aspect of the cancer problem has been studied experimentally by Mrs K S Bonser in inbred strains In agreement with other workers she arrives at the conclusion that there is no evidence of a general susceptibility to cancer for all organs As a rule, if a special susceptibility to cancer exists it is focused on one particular organ and strains of mice which possess such a special tendency to cancer in one organ often show a very decided resistance to cancer in some other organs During the past year two apparently well-authenticated claims had been made concerning the chemotherapy of cancer. It was stated that a simple organic substance (heptaldelyde) was able on injection to produce regression of transplanted and of spontaneous tumours in animals A similar claim had been made for a hydrolysate of heart muscle Both these substances have been examined for their therapeutic effects, but these claims could not be substantiated In Sheffield the Mellanbys have continued their studies on the distribution of the Rous-sarcoma virus after injection into the blood-stream. They find that it disappears from the blood very rapidly, being taken up by the cells of the different organs And this is true not only for fowls, for the connective tissue of which the virus is specifically pathogenic, but also for rabbits for which the virus is not pathogenic Professor Green has continued his investigations on the destructive effect of pyocyaneus toxins on tumour cells This effect is enhanced by combining the injection of toxin with that of an alkaloid (colchicine) which arrests cell division The experiments suggest the possibility that by a combination of such agents a more selective therapeutic effect may be obtainable.

A useful innovation of this report is a synopsis giving in non-technical language a summary of some of the work and its bearing on the problems of human cancer.

URINARY EXTRACTS INHIBITING GASTRIC SECRETION

SOME years ago Farrell and Ivy [1] showed that the inhibition of gastric motility and secretion that follows the ingestion of fats is due to humoral mechanism rather than to nervous or direct action, since inhibition is still produced in a transplanted and denervated gastric pouch when fat is taken by mouth. The humoral agent has been proved not to be a fat or one of the products of digestion of fat but a specific duodenal chalone, which has been called enterogastrone Next Sandweiss, Saltstein and Farbman [2] found that the injection of extracts of pregnancy urine successfully prevents the development of jejunal ulcers in dogs subjected to the Mann-Williamson operation This work has now been extended and such extracts have been shown to have the power to reduce gastric secretion but not motility. The urinary gonadotropic hormone of pregnancy, prolan, has been excluded as the active substance since the urine of normal males and females contain it, and lately Gray, Wieczorowski and Ivy [3] have suggested that enterogastrone consists of two fractions, one affecting motility and the other secretion, and that the active urinary extract is one of these fractions. Until now the enterogastrone extracted from the duodenum has not been used clinically because it always contains protein impurities which lead to the development of refractoriness if therapy is continued Urinary extracts can, however, be prepared free from protein impurities, and furthermore, they are some sixteen times as potent as the duodenal ones. It seems, therefore, that the urine may be a more effective as well as a more convenient source of enterogastrone, and that urinary extracts may have a place in the treatment of hyperacidity and peptic ulcers.

THE LAST THOUSAND FEET

THE summit of Everest apparently lies near the ceiling of man's endeavour from more than one point of view. Not only will he, if he reaches the summit without an oxygen apparatus, be asphyxiated, according to Henderson [1] and a host of others, but Matthews [2] says he will also freeze solid If he escapes these ills, Campbell [3] warns him that he will suffer from heart-failure and liver damage Henderson has tried, as many have done before, to calculate the oxygen requirements of the climbers near the top and to compare them with the oxygen actually available. He fairly assumes that the amount of oxygen that the men can obtain from the air decreases steadily as they rise Unfortunately he then proceeds to use as a basis for his calculation Somervell's statement that he and his companion had to "take 8 or 10 respirations for each step and stop to rest for a minute or two every 20 or 30 yards." This was certainly true in 1924 but things are different now. Greene [4] tells us, for instance, that in 1933 when the climbers were carefully acclimatised they needed only two or three breaths to a step and frequent halts were unnecessary So great an improvement partly invalidates Henderson's argument, though whether it is possible to reach the summit without additional oxygen remains in doubt Henderson dogmatically asserts that the inhalation of oxygen from an open-circuit apparatus is of no value during climbing, because all the oxygen is blown away by the tremendous volume of breathing, but the published statements of several mountaineers are in direct conflict with his opinion. Two types of apparatus were taken to Everest in 1938. Of these Lloyd [5] says that the closed-circuit type favoured by Henderson was unsatisfactory for reasons which are not yet clear It is obvious that were it possible to produce a light and efficient apparatus of the kind used for rescue work in mines its wearer could climb on Everest as fast as at sea-level But the problem is not easy, for no tests can adequately simulate conditions on the mountain, where repairs and adjustments to a complicated apparatus are nearly impossible. The other type taken was the simple open-circuit apparatus familiar to physiologists for many years, a development of which was described by Greene [6] in 1934 In this model a corrugated rubber tube was substituted for the more easily damaged canvas bag, and an alternative mouthpiece was provided in the form either of a mask or a tube to be gripped between the teeth In the 1938 expedition

an earlier and rather heavier model was chosen, the extra weight (allowing 1000 litres of oxygen) being nearly 3 lb It was calculated that when set to deliver 2 litres of oxygen per minute, it would "bring the climber down" from 20,000 ft to 20,800 ft, at which height the acclimatised man can climb at almost alpine speed In tests at a height of about 23,000–26,000 ft Lloyd [8] found that the open apparatus proved its value, not only in increasing the speed of climbing, but in lessening strain and fatigue Above 26,000 ft the increase in climbing speed became more and more apparent, especially on easy ground These results seem definitely to negative Henderson's conclusions, and unless the design of closed circuit apparatus can be radically improved the next expedition to Mount Everest would be well advised to depend on the open circuit inhaler

ASSAY OF ŒSTROGENS IN PREGNANCY

WHY œstrogen should be excreted during pregnancy we do not know, some day perhaps we shall find out In the meantime one of the things which may usefully be done is to measure the excretion in a number of individuals so as to define its limits and possibly to correlate its variations with pathological conditions The œstrone and œstriol in the human urine of pregnancy are free only to a small extent For the most part they exist in combination with inert substances in forms which are relatively, but not completely, inactive when assayed by their ability, on subcutaneous injection, to bring a spayed test animal into œstrus In the present state of doubt as to what is significant, the obvious course is to measure the amounts of free and inactivated œstrogen separately The latter may be released from combination by acid hydrolysis, and it then appears in such quantities as to be worth subdividing into œstrone and œstriol fractions In 1935 Cohen, Marrian and Watson [1] published curves showing the average urinary excretion of free and combined œstrone and œstriol for different periods of pregnancy in a number of women, thereby establishing a general rule The latest investigation of this kind is that of Dr Hain [2] of Edinburgh, who has made assays in 47 women during the latter half of pregnancy, recording not only the average findings but the individual assays in each case In many instances several assays at monthly intervals have been made on the same person This laborious work has disclosed great individual variations in the amount and behaviour of the urinary œstrogen, so great as to cast suspicion on attempts to associate diminished or increased excretion with types of abnormal pregnancy Apart from establishing a kind of prophylaxis against such premature correlations, it is doubtful if the research has added to the sum of theoretical knowledge *But this, as already suggested,* was hardly to be expected and in no way reflects upon the quality of the work or the necessity for doing it We emphasise this, because we believe that in certain particulars its presentation is open to criticism

In the table of results, for instance, the concentrations of combined and free œstrogen and the two fractions of the former are all expressed in milligrammes per litre Yet the sum of the quantities of œstrone and œstriol far exceeds the quantity of combined œstrogen of which they are the component parts This is manifestly impossible, and, although the explanation for the discrepancy can be guessed by studying the body of the paper, it is by no means obvious and in any event would probably be quite incomprehensible to those unfamiliar with the technicalities involved In mice, which were the test animals, œstriol has a different order of activity from that of œstrone when assayed by Dr Hain's method. Consequently, the increased œstrogenic activity of urine on hydrolysis is chiefly due to the œstrone liberated, the liberated œstriol, though many times greater in amount, having little effect on the assay The "milligrammes" of combined œstrogen in Dr Hain's table refer not to the actual collective weight of this group of substances, but to an equivalent and much smaller weight of standard œstrone against which its activity has been checked This value is therefore of the same order as the weight of the urinary œstrone after separation, which, within the limits of error of biological assay, is given in real milligrammes The separated œstriol, the assay of which is checked against a sample of pure œstriol, is also given, with the same reservation, in real milligrammes, but owing to the relative inactivity of œstriol the amount is large It is a pity that Dr Hain did not make this clear in her table of results, for this table is valuable and likely to be used for reference Confusion is not lessened by phrases in the text such as "œstrone, i.e., combined œstran," which implies (erroneously) chemical identity when quantitative similarity of activity is meant Control experiments, which seem to have been conscientiously carried out, deal with various difficulties—such as the separation of œstrone and œstriol without destroying the former, the optimal time for hydrolysis—points whose bearing on the results are readily appreciated. It is however not clear whether or not the slight œstrogenic activity of combined œstrogen before hydrolysis—possibly important when large amounts are present—is included in the preliminary assay of "free" œstrogen While the concentration of androgen in the urine is found to be less than that of the non pregnant woman, it seems to show no progressive change with the advance of pregnancy

The individual irregularities in the concentrations of excreted hormones raise the question whether the straightforward analysis of urine will prove to be of any more diagnostic value than (say) the simple estimation of urea It may be that the problem with which the kidney is dealing at any moment will also have to be elucidated If a guess had to be made, it would be that the final clinical criterion will be something in the nature of a renal or hepatic function test, in which the body is given a measured task to perform As Dr Hain points out knowledge of the metabolism of these hormones is in its infancy, so that a rational basis for such a test does not yet exist

PHARMACOGNOSY

THE Hanbury medal has been awarded to Mr T F Wallis, reader in pharmacognosy in the University of London The occasions on which the award committee (composed of the presidents for the time being of the Linnean, Chemical and Pharmaceutical Societies, and the chairman of the British Pharmaceutical Conference) has conferred this honour on a British pharmacist have been sufficiently infrequent to make the present choice outstanding This medal, a memorial to Daniel Hanbury, F R S (1825–75), is given for high excellence in the prosecution or promotion of original research in the natural history and chemistry of drugs the first recipient was Flückiger in 1881 The sum of the work done by Mr Wallis, chiefly in the Pharmaceutical Society's research laboratories during the past

1 Cohen S L., Marrian G F., Watson M. *Lancet* 1935, 1 674
2 Hain A M., *Quart J exp Physiol* 1939, 29 139

39 years. has been (1) to discover those details of gross morphology and of microscopical structure by which it is possible to identify correctly vegetable materials used in medicines either in the entire condition or in the form of powder, (2) to provide characters by which adulterants can be detected in foods and drugs, especially when in the powdered form or in broken pieces, (3) to discover general methods by which the proportions by weight of powdered materials —drugs or foods—may be accurately determined by means of the microscope, (4) to devise new optical apparatus and mechanical contrivances for use with the microscope in the study of powdered drugs, and (5) to devise new methods for the determination of the purity of certain chemical substances used in medicine and pharmacy. The results achieved by Mr. Wallis are recorded in thirty-seven papers describing original work which has made it much easier to maintain an efficient control over the purity and quality of food and drugs.

THE ILLEGITIMATE CHILD

TWENTY-ONE years ago the outlook of the infant born out of wedlock was precarious indeed: "The life of the unwanted baby is terribly easily snuffed out with his first sunset," wrote the editor of *Maternity and Child Welfare* in 1918. This wastage of life was not due to any inherent delicacy, but to the deplorable social and economic conditions which the child inevitably had to face, and the fact that the infant death-rate was at least twice as high among illegitimate babies as among the legitimate did not lie at all heavily on the public conscience But the losses inflicted by the war began to lead people to think that all young life, however lowly, was worthy of preservation, and those whose efforts to promote child welfare had hitherto met with indifference became all at once recognised as benefactors At about that time a conference held at the Mansion House led to the formation of the National Council for the Unmarried Mother and her Child Mrs H A L. Fisher, who became chairman of the council, has served in that capacity ever since, and has written a booklet entitled "Twenty-one Years" [1] to mark its coming-of-age, which was celebrated at the annual meeting held on June 13 at the Drapers' Hall.

At first the council encountered a great deal of prejudice and opposition; it seems strange to find that in 1918 nursing associations and maternity societies were only beginning to relax the rule that their nurses might not attend the birth of an illegitimate child Many people then still honestly believed that measures for the benefit of the unmarried mother were a challenge to the accepted standards of morality, and the education of public opinion, to promote which the council set itself, was an uphill task Gradually, however, sympathy was enlisted, and the fact rammed home that, whoever else was to blame, the child was innocent and deserving of help. The council soon found itself with an immense volume of work, and Mrs Fisher says. "Our story has been one of continuous overwork, brilliantly achieved, on the part of a staff which has never had enough room, enough money or enough help, but which nevertheless has made the council's life its own." The law bore no less hardly on the illegitimate child than did the actions of well-meaning but misguided moralists, and credit is due to the council for its untiring and fruitful efforts to secure reform of the bastardy laws Since its inception the legal position of the unmarried mother and her child has improved in many directions—for example, in the increased amount payable under an affiliation order, in the legitimisation of the child by subsequent marriage of the parents, and in the declaration of legal kinship between a mother and her illegitimate child in cases of intestacy. In all these reforms the influence of the council has made itself felt The council believes that it is almost always desirable to keep mother and child together where possible, and regards the solution by adoption as a good deal less than the best It has worked hard to promote the establishment of really good homes and hostels, and is in close touch both with Government departments and with other national and religious organisations Perhaps most important of all it conducts its work in strict confidence and with unsentimental sympathy

THE ROYAL COLLEGE OF NURSING

THE King's command that the College of Nursing shall henceforth be known as the Royal College of Nursing is timely, for we are beginning to realise that we are perhaps taking our nurses too much for granted and that the material return we offer them for their services is not commensurate with the gratitude we all feel. The college which was founded in 1916 to provide a central organisation for trained nurses was granted a royal charter in 1928 It has today a membership of some 30,000 trained nurses and a student-nurses' association of nearly 8000 nurses in training. The college has always recognised the importance to the community of an expert nursing service, adequate in numbers, quality and training to tend the sick and to safeguard the health of the public, and it has worked to improve the conditions in the profession and to attract the best kind of recruit. Our troubled times have added to its duties during the last year. Acting on behalf of the medical officer of health of the London County Council it is now responsible for the distribution of nursing personnel to the various sectors in which the hospitals in the London area have been grouped under the emergency hospital scheme, while in Scotland it is entirely responsible, under the Central Emergency Committee, for the recruitment and organisation of trained nurses to the civil nursing reserve

Medical men and women who have special opportunities for appraising the worth and work of nurses will recognise the fittingness of the new title.

CHEST LEADS IN CARDIOGRAPHY

THE physiological variations in the form of the curves obtained with a precordial exploring electrode are gradually being worked out in normal people, and comparison of these with the large number of tracings taken in cardiac lesions is clarifying the meaning of changes in these leads The subject is a complex one because, unlike curves obtained with limb leads, a small shift in the position of the electrode applied to the precordium may produce a big alteration in the form of the curve In order to assess the significance of a curve the exact position of the exploring electrode on the chest wall—especially its relation to the cardiac apex—and the range of normal variations obtained at this area, must be known Chest leads have been of greatest service in the diagnosis of cardiac infarction, though they may help in other lesions As with limb leads alterations in the direction and form of the T wave and deviations of the RS–T segment are important, but in the precordial lead special value is also attached to changes in the

orm of the mitral ventricular deflections or QRS omplex If a single precordial position only is used he area over the cardiac apex is generally considered he most reliable of all, and Robinson, Contratto and evine[1] find that absence of the R wave in the apical ead is almost invariable in the anterior type of ardiac infarction but rare in the normal heart and n other cardiac lesions They think that a small wave of less than 2 mm is questionable evidence f infarction They show that with only a small hift of the electrode medially from the apex the wave may diminish in amplitude considerably ow amplitude or even absence of R is found in ascites and left pleural effusion, the wave increasing r reappearing when the fluid is aspirated Inversion f the T wave in the apical lead is less constant and nore transient in anterior infarction, and is also ften present in cardiac lesions other than infarction —for example, mitral stenosis, high blood pressure nd syphilitic aortitis Even when the heart is quite ormal an inverted T is occasionally found in the pical lead In posterior cardiac infarction the pical lead gives no evidence not provided by traings with the ordinary limb leads Very similar conclusions re reached by Vander Veer and Edwards[2] after a tudy of 102 cases showing absent or small R wave n the apical lead. They found anterior cardiac nfarction in 67 cases when this wave was absent, he remainder being ascribed to luetic aortitis, oronary disease and possibly cardiac enlargement They agree with Robinson and his colleagues that disappearance of R is a change of long duration and hat it rarely returns to normal, the T wave changes being, on the contrary, of much shorter duration, but they regard inversion of T in lead 1 and in the pical lead as increasing the significance of a small or absent R wave in the apical lead

BIOPSY OF THE CERVIX

CARCINOMA of the uterine cervix, like that of other tissues, passes through an early almost symptomless phase before bleeding and discharge demand relatively late investigation By this time the growth may have become so extensive as severely to reduce the chances of cure Assuming that the two available therapeutic weapons, surgery and radium, have been exploited nearly to their limit, results can only be improved by earlier diagnosis The cervix is in many ways an ideal organ for this purpose it is readily accessible to inspection and palpation, and its relative insensibility to cutting and cauterisation allows a histological biopsy to be undertaken without admission to hospital and without an anæsthetic Wollner[3] of New York and Phaneuf and Belson[4] of Boston have independently drawn attention to the remarkable number of unsuspected carcinomas of the cervix that routine biopsy will reveal—in 59 examinations Wollner found 2 and in 100 Phaneuf and Belson found 10 Wollner recommends the removal of the lower half of the cervical mucosa to the point where it joins the healthy squamous epithelium of the portio vaginalis, and he uses a diathermy cutting loop Phaneuf and Belson use a sharp knife cauterising the incised area with caustic or electricity, a procedure that they say will also clear up nearly all cases of simple chronic cervicitis Biopsy, a method which is only suited to the specialist, cannot take the place of the ordinary pelvic examination, but it can be of great value in differentiating between early carcinoma and chronic inflammation in suspicious areas found with the vaginal speculum Wollner urges that every woman over 30 should have at least one routine tissue examination of the lower third of the cervix, and though this suggestion is likely to remain an unfulfilled ideal, it is no doubt a possible way of securing earlier treatment

A NEW DIRECTOR-GENERAL

WITH a view to further strengthening and coördinating the emergency medical services, the Minister of Health and the Lord Privy Seal have appointed Dr J H Hebb, C B , director general of medical services in the Ministry of Pensions, who is already acting as a principal medical officer in the Ministry of Health to take charge, as director general of emergency medical services both in the Ministry and in the Air-Raid Precautions Department of the Home Office

Dr Hebb will be assisted by a deputy, Lieut.-Colonel E T Potts, C M G , M D , who will act as headquarters officer in relation to medical personnel, assisted as regards nurses by Miss Watt, C B E , late matron in chief of the R.A.F , who will also be associated with the Central Emergency Committee of Nursing, the body responsible for building up the Civil Nursing Reserve Colonel Potts has had wide organising and administrative experience as assistant director of medical services at the headquarters of the British troops in France and Flanders in 1919 and 1920, and as assistant director of medical services, General Headquarters of the Army in India, from 1928 to 1933

Additional hospital officers have also been appointed Dr P H Oakley (headquarters) Colonel T H Scott and Wing Commander A J Brown (London region), Dr A E Tudor Hart (midland region), Lieut Colonel C L Dunn (north-western region), and Colonel H T Bates (north eastern region)

Lord HARLECH has been elected chairman of the board of management of the London School of Hygiene and Tropical Medicine He has also become a member of the court of governors of the school

At the annual meeting of the Coroners' Society of England and Wales held on June 29, Dr H BRETHER JACKSON, coroner for Croydon, was appointed president for the coming year Dr Jackson, who is also a solicitor, carries on a family tradition for his father was also Croydon coroner He conducted the inquest in the famous and lengthy "arsenic case" which attracted much attention a few years ago The society lost its secretary, Dr F Danford Thomas, this year, and he has been succeeded by Dr W Bentley Purchase, the North London coroner, with the never ageing Sir Walter Schröder as assistant secretary Both these officers have actually been in charge since Dr Thomas's death a few weeks ago

---

SEND OFF DINNER FOR MEDICAL WOMEN.—Miss Hilary Long and Miss Doris Brown whose appointment to the Women's Medical Service for India was announced in our issue of June 17, were the guests of honour at a dinner given by the Yorkshire Association of Medical Women on June 26, at which Prof. J R Flint and Prof Matthew Stewart spoke Miss Long is to be professor of surgery at the Lady Hardinge Medical College New Delhi, and Miss Brown is joining the gynæcological unit at the college

SPECIAL ARTICLES

WHAT MEDICINE OWES TO GREEK CULTURE

It was Sir Henry Lunn's achievement to enable the English-speaking peoples to take a less parochial and insular view of peoples of other lands On the occasion of his golden wedding two years ago Mr. H A. L. Fisher spoke of Lunn as an educator and a missionary You have, he said, rendered a very great service to higher education in this country by enabling so many students of Greek letters to visit the sunlit shores of the Ægean As chairman of the Hellenic Travellers' Club, Lunn had arranged in the early spring of this year a cruise to the highlands and islands of Greece, including visits to Epidaurus and Cos, giving opportunity for the study of the art of healing as it arose there His fatal illness on the preceding cruise prevented him from personally conducting this party, which consisted largely of doctors and their families, and from presiding at a series of lectures by medical men who had made a study of various aspects of Greek culture. Prof. J. A. Nixon (Bristol) discoursed with illustrative material on Greek athletics; Prof G E. Gask described the cult of Æsculapius and staged a scene from Aristophanes to make it topical; Dr. J. Dixon Comrie (Edinburgh) gave the fruits of a lifelong study of the Father of Medicine; and Sir Walter Langdon-Brown completed the series with a more general study of Greek influence in medicine. The lectures will appear in the Yearbook (1939) of the Hellenic Travellers' Club by whose courtesy we are able to reproduce here the substance of the discourses, along with some pictures collected for the most part on the cruise.

(B) Statue of Telesphorus, god of convalescence, in the National Museum at Athens It was Telesphorus who gave Aristides the healing balsam at Pergamos The hooded figure with closed lips suggests the silence and secrecy to be observed by the physician.

The Cult of Æsculapius

(PROFESSOR GASK)

Æsculapius, the mythical god of healing, was taught that art by Cheiron, the centaur, and had two sons, Podalirius and Machaon, who fought at Troy and are the supporters of the coat of arms of the Royal College of Surgeons His cult spread over Greece and the islands as far as Asia Minor and Rome. Hundreds of temples, called æsculapia, were erected to him (often in association with Hygeia and Panacea), the most important being at Epidaurus, Athens, Cos and Cnidos The chief item in the ritual was incubation —i.e, the patients slept in the temple to have healing dreams. This was done after purification and sacrifices. During the incubation harmless sacred snakes crawled among the patients and licked their sores The importance of these snakes is shown by what happened during the plague in Rome in 292 B C. After consultation with the Sibylline books an embassy was sent to Epidaurus for help and brought back one of the snakes. As they were sailing up the Tiber, the snake slipped overboard and swam to what is now the island of San Bartolomeo This was regarded as a sign that a temple to Æsculapius should be built there, and the island was given the form of a trireme to commemorate the voyage When the river is low, remains of the ancient stones can still be seen, together with what probably is a representation of Æsculapius There is still a hospital on this island and tradition says that here, about A D 1120, Rahere lay sick with a fever and dreamt that he would be cured if he built a hospital on his return to London So one may amuse oneself by thinking that there is a connexion between St Bartholomew's Hospital in Smithfield and the old healing gods of Greece

Common Seal of the Royal College of Surgeons of England. Supporting the armorial bearings are the two sons of Æsculapius: Machaon holding a broken arrow and Podalirius with a staff entwined by a serpent.

Though the cult had such a vogue, the subtle minded Greeks could laugh at it, and it was the subject of one of Aristophanes's comedies the "Plutus," which is thought by scholars to give a good description of what went on in a temple of Æsculapius The next reliable information comes from the "Sacred Orations" of Aristides in the second century A.D., when, in addition to the previous ritual, the treatment included dieting, bathing and exercise. Aristides was given prescriptions, such as balsam, to be used on leaving a hot bath for a cold one; on a cold frosty night he had to rub himself with mud, run three times round the temple, and wash himself in the well. There is no evidence that any serious medicine was practised at these temples, and some of the old paganism became attached to the Christian religion.

Photo G. H. Ward.

The abaton or sleeping place in the æsculapium at Pergamos. The row of broken marble columns once supported the roof, the spaces between them leaving the patients open to the distant view and to the visit of the healing snake

Thus St Cosmas and St Damian were reputed to have miraculous healing powers, and incubation was practised at their shrines, at certain seasons crowds of sick still frequent the church at Ayassos on the island of Mytilene, sleeping in the church or its courtyard

The island of Cos, the birthplace of Hippocrates, is the site of a very famous æsculapium, and it is believed by many that Hippocrates received his training and derived his inspiration from it—a belief that is probably incorrect, for there is no taint of magic or superstition in his teaching. Further, all the available archæological evidence suggests that the æsculapium at Cos was *not* established until after Hippocrates's death

Hippocrates

(DR COMRIE)

Hippocrates is said to have been born in Cos in the year 460 B.C., the son of a physician named Heraeloides. He was trained in medicine first by his father in Cos and later in Athens where he spent most of his life in the practice and teaching of medicine. Nevertheless he travelled much and visited Thessaly, Thrace, Macedonia and possibly Scythia. On one of these journeys he died at Larissa, in Thessaly, probably about 375 B.C. at the age of 85.

The Hippocratic writings, on which the fame of Hippocrates rests, consist of about seventy works dealing with very different topics, theoretical and practical. Some give clear cut pictures of disease with the appropriate treatment, others are mere notes intended perhaps as headings for a course of lectures. Some are perfectly simple and easy to follow, others are confused and barely intelligible. All are in the Ionian dialect, but internal evidence shows that they were composed by different writers at different periods. Among them, however, stand out about a dozen which bear the stamp of genius, these indicate an author with great power of observation, clarity and simplicity of exposition, they have been recognised by authorities as the genuine works of one man, who is assumed to have been Hippocrates. Those treatises, regarded as the genuine work of Hippocrates and translated by Francis Adams for the Sydenham Society in 1849, include "On Ancient Medicine," "On Airs, Waters, and Places," "On the Prognostics," "On Treatment in Acute Diseases," "The Epidemics" (books I and III), "On Injuries of the Head," "On Surgery," "On Fractures," "On the Joints," "On Setting Joints by Leverage," "The Aphorisms," "The Oath," "The Law," "On Ulcers," "On Fistulæ," "On Hæmorrhoids," and "On the Sacred Disease" (epilepsy). It has been suggested by W. H. S. Jones that the whole collection of "Hippocratic writings" formed the library of the Hippocratic school of medicine at Cos. These works have passed through the hands of a host of commentators, of whom the greatest was Galen (second century A.D.). The earliest commentary that has survived (as a tenth-century MS.) is that of Apollonius of Citium (*circ.* 100 B.C.). The earliest MS. of Hippocrates now extant is a ninth century codex of the Laurentian library.

The fundamental principle of Hippocratic treatment was that the cure must be effected by nature, and that the best the physician could do was to see that nature got a chance and to assist the natural cure. The remedies were chiefly purgatives and febrifuges, 236 plants are mentioned in the Hippocratic writings. Great emphasis was laid on prognosis ("in this way you will justly win respect and be an able physician"). The importance of Hippocrates is that he first separated rational medicine, as practised by the members of the Asclepiad guilds, from temple medicine, conducted by the priests. The critical Athenian mind had already begun to see through the impostures of the priests, as shown by

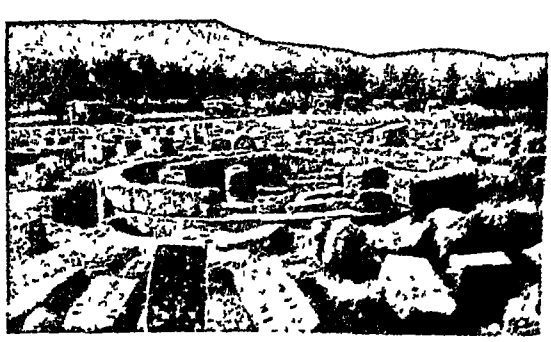

Photo G. H. Ward.

The tholos, close to the æsculapium at Epidaurus, where the sacred snakes were kept. It is arranged in concentric circles, the outside one 37 in diameter, and is 12 ft. deep. Note the seat for the attendant

Aristophanes in his "Plutus." Hippocrates insisted on the complete banishment of superstition and on the rational treatment of all diseases instead of by ablutions and incantations, as if they were inflicted by the gods This attitude is clearly defined in his treatise on epilepsy: "It is not any more divine or more sacred than other diseases but has a natural cause, and its supposed divine origin is due to men's inexperience and to their wonder at its peculiar character."

Greek Athletics

(PROFESSOR NIXON)

In no country have athletic sports attained the same degree of national importance as in Ancient Greece The games festivals, although not consciously instituted for such purposes, soon came to serve two great objects: first, they promoted physical fitness and dexterity in martial exercise, secondly, they led to frequent assemblies of the inhabitants of all the states of Greece, thus favouring national unity. Even states at war with one another suspended hostile operations during the games. Competitors and spectators could travel safely to the festivals, and no warlike weapons were allowed to be brought into the sacred precincts The great athletic celebrations, such as the Olympic games, must have developed slowly from the funeral games, such as those described by Homer as having been held in honour of Patroclus, at which all the contestants were given prizes as memorials of the dead. In later times all competitors at Olympia underwent thirty days' training at Elis under the supervision of the Hellanodicæ, who themselves underwent ten months' training in their duties. The training was severe, absolute obedience being enforced, when necessary, with the rod. The Hellanodicæ tested the athletes, rejected the unfit, and graded the entrants in age-groups, after satisfying themselves of their parentage and claims to compete The earliest extant records of the games concern the 28th olympiad of 776 B.C. (each olympiad being a period of four years).

Down to the end of the sixth century B.C. the athletes were amateurs and the Greeks were truly a nation of athletes Their training was natural, elaborate rules for exercise, diet and sleep not yet having been introduced. But the typical athlete of the sixth century was the strong man—boxer, wrestler, or pancratiast In the fifth century B.C specialisation had not yet begun; the best athlete was an "all-rounder," and artists and sculptors set up a standard of physical beauty. Style and grace in athletics were more admired than mere strength. This love of beauty checked the growth of specialisation and the encroachment of professionalism But specialism came in with the advent of professional trainers. Athletes were selected and trained for particular events The new training concentrated on particular exercises calculated to develop limited groups of muscles, with the result that in the statues and drawings of these later athletes different physical types can be recognised as adapted for different sports From the professional trainer it was but a short step to the professional athlete, and with his arrival amateurs retired from the competitions Training for athletics ceased to be a useful training for war, and complaints to this effect were heard: Epaminondas declared in the fourth century that fleshy boxers and pancratiasts were of no use as soldiers and dismissed them from his army; Philopoemen, two centuries later, refused to cultivate his natural gift of wrestling, saying "better wrestler, worse soldier"; and Galen, in the first century A.D., although he thought highly of bodily exercises, opposed athletic training, saying that the health of athletes was most deceptive and precarious and their strength of no use for practical purposes At the time of the Peloponnesian wars in the fifty century B.C the mass of the people were no longer athletic, although they were eager spectators at the professional competitions Nevertheless the ideal of physical fitness was firmly implanted in the Greek mind, and it was held that the fitness of the body had an important effect on the character and the mind

In modern times there has been a revival of the cult of physical fitness, yet we are not sure what constitutes a state of perfect fitness—still less how we may achieve it. Some seek it through exercise and still more exercise; but the effects of athletic exercises show us that it is not given to everyone to develop skill in games, however much he may practise A more rational spirit is

The stadium at Delphi which is 190 paces long and 28 paces across The site was too steep for chariot racing which took place in the valley far below.

entering into the search for physical fitness World wide inquiry is being made into its physiological and psychological foundations Good food and healthy conditions of living are being recognised as no less important than muscular exertion

Greek Influences in Medicine

(SIR WALTER LANGDON BROWN)

The eternal youth of Greek thought, although at times buried for centuries, has at intervals burst forth to the surface like a stream to refresh the deserts of scholasticism and to sweep away outworn traditions If the virtues of the Greek spirit are those of inquiry, moderation, reason and freedom, its vice was that of uncontrolled speculation, as best exemplified in Plato's "Timæus," which gives a complete design for the universe, including an inverted conception of evolution—the descent of animals from man Such teleology undoubtedly hampered the progress of science, since it was eagerly adopted by the authoritarian spirit of the Middle Ages The main stream of Greek thought disappeared underground when Justinian I closed the school of Athens in A D 529 Before this happened, however, Rome had constructed an aqueduct which diverted much of the stream to herself, and in the reign of Marcus Aurelius the famous Galen was the

[From E Norman Gardiner's Greek Athletic Sports and Festivals Macmillan & Co 1910

Pan-athenaic amphora showing four amateur runners reaching the turning point It illustrates the correct (alternate) attitude of limbs as early as the sixth century B C

great exponent of Greek medicine After him all scientific inquiry seemed to pass into outer darkness

Perhaps the seventh century was the darkest of all Such light as still shone was provided by the Arab school In the twelfth century medicine, based on the teaching of Averroes, was by far the chief faculty of the school of Salerno, and for several centuries Salerno stood almost alone in its rational methods and in its conservation of Greek and Latin treatises. Early in the thirteenth century Frederick II, who was keenly interested in science, insisted on the students there, after a preliminary study of logic, dissecting corpses (which he had no difficulty in supplying), combining this with clinical work and the reading of Hippocrates and Galen Students were not granted appointments until they had practised a year beside an experienced physician Unfortunately Frederick's quarrels with the papacy greatly hampered his educational reforms and when he died in 1250 theological fetters were bound more firmly again on the growing mind of the thirteenth century A hopeful dawn ended in the twilight of the Black Death

Thus we approach the second phase of the Middle Ages, in which authority was felt to be necessary for the stability of Europe The spirit of domination spread to science with disastrous results The Dominicans decided to abstain from the study of physical and medical science and are represented on the walls of the Spanish chapel in Florence as the dogs of the Lord (domini canes) trampling on Averroes, the sole link between ancient and modern medicine The only thing that saved medical science during the next two centuries was surgery, which the physicians tried hard to suppress, with the result that medicine lost touch with facts and the physician too proud even to examine his patients, deprived his brain of the subtlest machine in the world—the human hand The stream of Greek thought seemed now not only to be contaminated but also to have become stagnant, yet good came out of evil when the capture of Constantinople by the Turks in 1453 set free far more abundant original Greek literature The new learning was spread by the new invention of printing The Renaissance came to Cambridge in the person of Erasmus, who established there the study of Greek He was accompanied by John Siberch, founder of the first printing press to be set up in Cambridge, who published Thomas Linacre's commentaries on Galen

Thus the Greek tradition was revived by Linacre, the father of academic medicine in England, who also induced Henry VIII to found the Royal College of Physicians of London in 1518 and established lectureships at Oxford and Cambridge in 1520, which stimulated Henry to create regius chairs at those universities in 1540 With such a splendid start it is disappointing to discover how little was achieved This was because the new learning was simply an authoritarian exposition of the old medicine The regius professors merely read the corrected versions of the writings of Hippocrates and Galen, and no attempt at new observations was made Men like Caius and Harvey still had to go to Padua for their medical training It was not until Harvey introduced the new method of experiment that a real change came He had been influenced by Bacon's method of inductive reason, and Bacon in his turn by the physical experiments of William Gilbert, president of the Royal College of Physicians in 1600 Thus observation, reasoning and experiment entered into medicine and replaced mere authority But the clinical application of the method of strict observation was due to Sydenham It is interesting to note the sequence of the new ideas first Gilbert's physics, then Harvey's anatomy and physiology, and then Sydenham's clinical observation—a genealogical tree of medical science which the student of today has to climb in his first, second, and third M B. examinations

Each of these revivals of medicine through the rediscovery of Greek thought was a conscious return, but the modern return to certain features of the Æsculapian cult has been unconscious As early as 500 B C Alcmæon had insisted that "health depends on harmony, disease on discord, of the elements within the body" We are now prepared to regard disease as the sum total of the uncomfortable reactions (dis ease) of a patient to some perturbation in his external or his internal environment—possibly in both Thus an anxiety neurosis and a bacterial infection are equally diseases, but the form of the reaction is largely determined by the make up of the patient In Mohr's words: "There is no such thing as a purely psychic illness or a purely physical one, but only a living event taking place in a living organism" So we find ourselves after twenty-five centuries, standing where Alcmæon stood

Cleanliness, fresh air, analysis of dreams and psychological explanation were the cardinal tenets of the Æsculapian cult, and all of them were lost by medicine until recently. Today we have returned to the cult of Æsculapius and are his faithful disciples.

Watching the ebb and flow of the tides of Greek influence through the centuries provokes a sombre reflection. If the Middle Ages considered truth to be static, we believed liberty of thought and the right of free investigation to have been permanently established. With something of a shock we have had to realise that the price of liberty, even liberty of thought, is eternal vigilance We see cause to dread what H. G. Wells called "the incursion of the clumsy lout" This century may have adopted as a slogan "Propaganda is more powerful than truth," but we must never bow the knee to a Baal that would make natural science into national science.

PARIS

(FROM OUR OWN CORRESPONDENT)

OLD-AGE PENSIONS FOR DOCTORS

When M Pomaret some years ago proposed compulsory retirement at 65 for members of professions, sharp protests were made by lawyers, doctors, and engineers Owing to lack of funds the scheme was dropped; but a new scheme has been planned, again sponsored by M Pomaret, but this time with the collaboration of Dr. Cibrie, secretary of the *Confédération des Syndicats Médicaux Français*, which represents 21,000 doctors out of about 27,000 in France It embraces the whole profession on an insurance basis The premium paid by the doctor would be compulsory during the whole of his time in practice, but the age of retirement would be optional after 65.

The premium would be about 3000 francs a year, with a diminishing reduction during the first years of practice and a progressive reduction after 60 The monthly income, starting at 1000 francs during the first years after the scheme comes into force, would later rise to 2000 francs or more A clause has been inserted to safeguard against possible alterations in the value of money. Only half the annual premiums would be capitalised, the other half being shared each year. Provisions have been made for widows and children

The plan has been accepted by the majority but is criticised sharply by a strong minority, who think that the pensions freely subscribed by ancient professional corporations are better from both the financial and the ethical standpoints. The present plan, which falls in with the social ideas of most politicians, has every chance of being passed by both chambers

NEW LUNACY BILL

The confinement of lunatics is governed in France by a law of 1838 which has never been changed. Since 1870 eleven attempts have been made to modify it, but each time the intended improvements proved to be worse than the old law. A new bill, which has just been passed by the chamber of deputies, keeps nearly all the items of the 1838 law but introduces the principle of voluntary admission and legalises the status of the "free insane hospitals" to which patients are admitted without being certified. The first example of a hospital of that kind, the Hôpital Henri-Rousselle, was founded by Dr. Toulouse shortly after the late war.

A recent decree changing the name of the *asiles d'aliénés* to *hôpitaux psychiatriques* has given much satisfaction to those who have long been trying to get the public to regard insanity as mental disease and not a disorder of conduct

"CARNET SANITAIRE"

M. Rucart, minister of public health, has introduced the use of a book (*carnet sanitaire*) intended to record the medical history of its owner. It is given free by municipal authorities at the birth of a child. At schools and hospitals it is given or sold according to the private means of the person concerned. No name is written on the book but only a number referring to a register held by the distributors, so that, if lost, it can be returned to its owner without breach of confidence. At present the booklet has commended itself more to the sanitarian than to the private practitioner whose interest it was hoped to elicit.

FIRST STAGE OF GASTRIC CANCER

Dr R. A. Gutmann, consulting physician for gastro-enterology in Professor Gosset's surgical clinic at the Salpêtrière, has evolved a method of early diagnosis of cancer of the stomach by a close confrontation of clinical study, therapeutic tests, and radiography. In his recently issued book he publishes cases in which the surgeon at operation could palpate nothing abnormal and hardly anything abnormal could be seen on the open viscus by the naked eye, but microscopy alone proved the diagnosis. Professor Gosset claims in the preface that this work is the first to be published on the initial phases of gastric cancer.

Dr. Eisendrath, of Chicago, has died in Paris, where he had lived since the war. He was consulting urologist at the American Hospital in Paris and much appreciated by the American colony.

UNITED STATES OF AMERICA

(FROM OUR OWN CORRESPONDENTS)

MALNUTRITION

In an address to the tenth annual convention of the New York State Dietetic Association, Dr. Frank G. Boudreau reviewed the evidence of inadequate nutrition in the United States It was found in investigating an outbreak of scurvy in Maine, he said, that half of the 4000 children studied had had no milk for two years The blood ascorbic acid was estimated in 95 children and 66 of them had less than the normal concentration and 44 had less than 0·5 mg per 100 c cm. Of 155 children admitted to the Toronto Hospital for Sick Children, only 16 per cent. had ascorbic-acid levels believed to be consistent with good health

Nutritional œdema, due to deficiency of protein, is found in 15 per cent of patients admitted to a large Georgia hospital, while 35 per cent of these patients have nutritional anæmia. Last year, Dr Boudreau said, there were at least 100,000 cases of pellagra in the South. He referred also to a dietary survey of low-income families in Toronto which showed that "on the average the diets of the women and children were deficient in every important ingredient including total calories." The explanation

of the deficiency in calories is not that people cannot buy enough bread and sugar but that the type of diet which they are able to afford is unappetising In urging the needs for a well organised programme of improved nutrition, Dr Boudreau said "we are beginning to appreciate that the effects of nutritional deficiency are more serious and permanent that we had believed, and on the other hand that the benefits of an abundantly adequate diet are greater than we had any reason to expect"

VALUE OF ROUTINE RADIOGRAPHY

In 1932 Mills and Stewart[1] tested 353 patients in the Swedish Hospital in Minneapolis with the intradermal tuberculin test and then examined the 67 positive reactors radiologically Of the full number tested, 1 4 per cent were found to have reinfection type tuberculosis In 1935 Hodges[2] made a survey of 1101 consecutive admissions to the Michigan University Hospital or to its outpatient clinic during a period of a fortnight and found that 1 3 per cent of the patients had significant chest disease and 0 5 per cent pulmonary tuberculosis which would have been undiscovered without radiography These results were quoted by E X Mikol and R E Plunkett in a paper read to the American Sanatorium Association in Boston on June 26 They had remarked that some 10 per cent of the deaths from tuberculosis in upstate New York in 1936 and 1937 took place in general hospitals which had no special provision for the care of tuberculous patients Of the deaths from pulmonary tuberculosis, which comprise nearly three quarters of the group, no less than 61 per cent had not been recorded as cases of tuberculosis at the time of their death It was thereupon decided to make a survey of a random sample of the hospital population of New York state Each hospital was allotted a number of X ray films varying from 250 to 500 according to the number of admissions and was requested to make a single flat film of the chest of every patient 15 years of age or over admitted, excluding only those known to have tuberculosis, those admitted to a tuberculosis service, outpatients, and those too acutely ill to be disturbed Due to unforeseen administrative problems, consecutive X rays were found to be impossible, but Mikol and Plunkett believe that this fact has not seriously affected the unselected nature of the sample

Of 4853 films studied, 2 6 per cent showed evidence of reinfection type of tuberculosis, 1 1 per cent showed radiological characteristics of clinically significant tuberculous lesions and in 6 additional cases indications of significant tuberculosis were found but the diagnosis could not be confirmed because the patients had been discharged Of the 51 clinically significant cases, 24 had been regarded as suspicious by the visiting staff However, in 27 cases, or 0 6 per cent, the radiogram provided the first suggestion that the patient might have tuberculosis Applying this figure of 0 6 per cent to the adult admissions to hospitals throughout the whole United States for the year 1937 an estimate of 40 000 cases of pulmonary tuberculosis is reached The potentialities of reinfection both of the hospital staff and of other patients is the first practical lesson to be drawn from this research The authors also draw attention to the possibility of utilising the general hospital as a medium of case finding in tuberculosis, and finally they point out that routine radiography is of value in disclosing non tuberculous thoracic conditions

MEDICINE AND THE LAW

The Defence of the Split Mind

A LEGAL contemporary expresses the misgivings of the legal profession over the defence of schizophrenia in criminal trials Its comments are made in connexion with a recent prosecution at Nottingham assizes A boy named Hayter joined the army when 16, giving his age as 18 At the age of 20, being a private in the Royal Army Ordnance Corps, he set fire to stores and tyres at the Chilwell depot, causing damage to the amount of £36,000 There was no suggestion that he was connected with any subversive movement Dr J H Murdoch, the medical officer at Lincoln prison, who attributed Hayter's act to the conditions of the "split mind," said that the accused felt that the social system of the country was not as it should be and he desired to register a protest against it, he needed care and control The judge sentenced him to detention in a Borstal institution for a period of three years, adding the philosophic reflection that he wondered what would have happened to Hayter in some other countries if he had there done the damage which he did at Chilwell

The legal journal to which reference has already been made asks how far the defence of the split mind is to go The recently convicted members of the I R A, it observes, might also claim to justify their actions on the ground that things are not as they should be and that a man must make his protest The lay press evinces a little interest when an accused person can be described as another case of Dr Jekyll and Mr Hyde Barristers who must find something to say in mitigation of sentence are grateful for any material Any young man who is fed up with the discipline of the army and who occasionally feels impelled to kick over the traces may be comforted by the attribution of his wayward impulse to some high sounding scientific cause But schizophrenia has not yet made much headway with the bench, even though it may be studied in the prison

THE LANCET 100 YEARS AGO

July 6, 1839, p 553

A quotation from William Heberden

"The deference which is sometimes required in physic to the authority of the ancients, would incline any one to suspect that the improvements in the art of healing had not kept pace with those which have been made in other branches of natural knowledge Philosophers have long ago thrown off Aristotle's tyranny, yet some physicians still choose to wrangle about the meaning of the ancients, rather than to consult Nature herself Are they afraid of approaching her immediate presence, without making use of the intercession of Hippocrates and Galen? And is that reverence to be still paid to her once faithful ministers, which is properly due to Nature alone not withstanding all that Bacon, and Harvey, and Newton, and our other great reformers have witnessed against this mistaken veneration? In works of genius the ancients are unquestionably our superiors and best patterns but in that sort of knowledge which depends wholly upon experience, the latest writers must in general be the best Experience may, in politics and morality, be called the teacher of fools, but in the study of nature there is no other guide to true knowledge accordingly the practice of physic has been more improved by the casual experiments of illiterate nations and the rash ones of vagabond quacks, than by the reasonings of all the once celebrated professors of it . . "

GRAINS AND SCRUPLES

Under this heading appear week by week the unfettered thoughts of doctors in various occupations. Each contributor is responsible for the section for a month, his name can be seen later in the half-yearly index

FROM A WOMAN PUBLIC-HEALTH OFFICER

II

LIKE Their Majesties and Christopher Columbus, and several of my predecessors in these pages, I have travelled to the New World and found it good. Though my voyages made less stir than those of some of the above-named, I doubt if any of the travellers enjoyed themselves more. Believe me, the best way to visit a new country is to have good enough official and social introductions to open the door to anything you want to see—and yet to be sufficiently unimportant to slip off "truly exploring" by yourself whenever the mood takes you Only thus can one hope to include both the Great Ones of the Earth and the "nice people, with nice habits, but no money at all" who constitute the bulk of humanity

My journey to the States as the guest of a great philanthropic trust fund began rather inauspiciously in Canada. I nearly disgraced myself by saying to a learned professor, introduced as a "follower of Dr Watson": "I'm so glad to meet another Sherlock Holmes fan over here"—fortunately this was mistaken for an example of English humour, but in sober truth I had underestimated the importance of the Watsonian school of psychology. Later one learnt better. . . . In Toronto one found an extremely well-organised system of public-health and psychiatric services, which I mention because the English medical visitor often misses them Here also is a remarkably interesting court—unique, I believe, in the British Empire, for it is presided over by a woman judge, and a doctor not a lawyer at that. Her jurisdiction seemed to include all crimes except murder and treason, and she dealt with all delinquent women and children, all men charged with offences against women or children, and men who misguidedly got a woman pal to assist when "on a job" Never have I seen such a ruffianly clientele in any court—during a morning spent beside the judge on the bench one learned quite a lot. . . . In the train that took me over the U.S.A. border an innocent query to the conductor brought the pitying question: "Say, sister, where are you from?" "From London" "You must sure mean London, *England*, or you wouldn't be so ignorant" (I'd forgotten London, *Ont*.) That's a good line for a British visitor to remember. . .

* * *

One has almost forgotten that in 1927–28 the U.S.A. were enjoying a marvellous boom period What a joy after the gloom of post-war England to see a country bathed in material prosperity! It was like watching children at a really good Christmas party. Even the women prisoners in the night courts had better fur coats than I, the working men had splendid food and decent little homes, and, best of all, the young had justifiable hope in their hearts that the world had a use for them and their labour, nor were the standards wholly material, for I can swear to an immense communal feeling, a passionate desire for education, and a real love of beauty and culture One saw museums fit to enshrine great masterpieces of art, hospitals that towered to the sky, and millions poured out in charities. And, if much of this wealth has vanished like fairy gold, America can at least remember that she used her money not ignobly when she had it—and would do so again

A fly in the ointment was the comprehensible but maddening incapacity of certain of my hosts to understand why so many English workers perversely persisted in being unemployed Less excusable was the way in which many highly placed British visitors played up to this attitude and left a trail of disgusting slanders on the broken men of the Clyde, the Tyne, and South Wales. I caught one at it in Chicago and can only regret that he escaped—though narrowly—with his life

The work in child guidance that one had specially come to see had flourished apace in the general prosperity. Nothing lends itself more to sheer quackery or to humourless extravagances than does "psychology," especially when applied to children Examples were not far to seek, but the clinics to which we were shepherded by our hosts of the Commonwealth Fund were for the most part as austere as they were costly Only the best in the way of academic qualifications and scientific methods were good enough for the "maladjusted" child, and the whole scheme was organised with a quite uncommon common sense Had we anything to learn from them? our hosts asked modestly. Definitely we had And they have given since with both hands that Great Britain might reap the benefit of American ideas and experiences.

* * *

Although in 1927 the word "depression" meant less to the average American than "hang-over," there were plenty of snags in the stream of prosperity. One of them was the eternal problem of the "melting-pot" No amount of reading or intensive study of the movies prepares one for the reality Wait till you see those hordes of strange flat faced industrial workers—from countries that one never heard of till Hitler taught us Central European geography Wait till you drive along a three-mile avenue in Chicago and look in vain for a white face on the crowded side-walks Or come and scan the long charge-lists in the juvenile courts with their patronymics drawn from half the races in the world. Then you may begin to understand the difficulty of tackling any social or political question in such a composite nation . . And yet it is a nation . . . Jane Addams (one of the great people who didn't disappoint) showed me maps which demonstrated how the racial constituents of her neighbourhood in Chicago had completely changed three times in her lifetime (The races in America tend to live together in agglutinated masses, and where the edges touch crime and discord are rife) Now in 1927 had come a new wave, a horde of Mexicans imported as cheap labour for the then booming industries I was asked to help at an "Americanisation party" for them and found it very different from the flag-wagging affair one had supposed The very shy older people, who were with difficulty coaxed in from the street, were given their favourite foods and drinks, and once wreathed in smiles were invited to show what they could do in the way of native handicrafts, folk-songs, and cookery. Far from being

hastily mechanised they were encouraged to pass on their native culture to their own children, to enrich the American heritage. "It's a shock to most of these poor undervalued folk to learn that they have anything worth while to give us," said Miss Addams. "Heaven forgive us, we've only just realised it ourselves." The main trouble very often is to persuade the European peasant to give enough freedom to his American born child—and to persuade the child that even a foreign speaking mother sometimes knows best. From the clash comes a great part of American crime.

Certainly the American child, if tough, can be very tough. A boy on remand was expounding to the court psychiatrist the mysteries of the Forty Club, whose initiation fear was—and perhaps still is—to steal a car of a greater value than a Ford. "Why the *Forty*," he was asked, "Aw, sap! Where was you raz? Never heard of Ally Babba?" We—the psychiatrist and I—duly found the headquarters of the Club that night in a squalid side street with costly cars parked round the door to witness that the young neophyte did not lie.

Not less baffling was coloured Sadie, aged 8 plus, with two pigtails, great innocent eyes, and an appalling record of varied misdeeds. Angelic at first, she became very naughty during a psychological test, and the doctor mildly remarked that he would hate to see a little girl of his own behave like that. "Yo go home and hand dat stuff to yo wife," she shot out at him. Seeing that my presence was unwelcome, I left the room and learnt later that Sadie immediately sidled up to the doctor, thrust a pencil into his hand and begged "Now, yo play a game wid me!" The doctor wisely asked further details—"See which of us two's can writ down de mos' bad words. Ain't dat a *cute* game?" One doubted whether a team of professors of psychiatry and psychology, even if reinforced by an old Nannie with a slipper, could deviate Sadie from her appointed path through life.

* * *

The chief difficulty, however, with which child guidance clinics had not infrequently to contend was a certain sketchiness in the ethical standards of the community in which they worked. Children are not fools, they watch what their elders do rather than what they say, especially if the deeds rather than the good advice accord with their natural instincts. At one clinic I visited it appeared that a large adjacent building was used as an illicit brewery (under Prohibition) and as a depot for stolen motor-cars. The doctors or social workers while examining their little charges (accused perhaps of stealing a few cents) could watch a highly skilled gang of negroes dismantling the stolen cars. One day a magnificent Hudson Super six was driven in, and the psychiatrist could bear it no longer. He telephoned the police, who took over an hour to arrive—and then could find no car on the premises. Later he learned from amused colleagues that the whole place belonged to one of the highest officials in the city. The doctor told me he meant to quit. "I can't make sense of it all. I wonder if the kids can."

This really tragic (though diminishing) factor in the American scene did bring home the importance of encouraging decent people to do the drudgery of public administration—and of not crabbing them too hard when they are at it. I can never hear the stock sneers against Parliament and municipal bodies without wishing the critics could get the administration they are really asking for. If there is no tradition that honest men should give this kind of public service, and if the supply of honest men slackens, then crooks come into their own. And if public office once gets a really bad reputation decent men dare not take it. From this vicious circle America is struggling hard to extricate herself.

PANEL AND CONTRACT PRACTICE

Unwise Comment

A CASE heard before the London medical service subcommittee shows how careful hospital officers should be in criticising, however mildly, the treatment given by doctors outside. A man had been treated by his insurance practitioner on many occasions for rheumatism, lumbago and the like. Last December he went to the doctor and was diagnosed as suffering from sciatica, for which he was treated first with medicines and then for a fortnight with electricity at a clinic. A few days later the doctor visited him and found him to be suffering from bronchitis, the leg being rather better. Under treatment the bronchitis improved but the pain in the leg became worse, and the doctor suggested admission to hospital. After about a week he was admitted, and the condition was there diagnosed as right-sided femoral thrombosis. The man's own story was that on his admission his leg was swollen from foot to thigh, and that the hospital doctor told him that the ointment which he had been applying, which had been prescribed by the insurance practitioner, was useless for the treatment of that condition. In a letter to the insurance practitioner the hospital authorities said they were unable to determine whether the man's sciatica had any relation to the thrombosis.

The insured man and his wife complained to the committee that the practitioner had been negligent in his treatment in that he had wrongly diagnosed the condition present, but the committee found that the treatment provided by the practitioner was proper and adequate for the condition which he diagnosed, a diagnosis which was fortified by the previous medical history. They expressed regret that the man had been told on admission to hospital that the treatment given was not suitable, and they were doubtful whether any question would have been raised if this remark had not been made.

The period between the man's first visit to the doctor and his admission to hospital was just over two months, and clearly thrombosis was not present for all that time. While the practitioner may not have diagnosed the new condition—and he said quite frankly that he did not disagree with the hospital opinion—it would be intolerable if practitioners were held guilty of negligence merely because they made a wrong diagnosis. All that any doctor can be expected to do is to apply "reasonable skill and care in the treatment of his patients" and this is all that the regulations require of him.

Contraceptives

In answer to a question about the position of insurance practitioners who are asked for advice about contraceptives, the insurance acts committee of the British Medical Association have expressed the opinion that if the condition of the patient is such that the practitioner should give contraceptive medical

treatment or advice, such treatment or advice would be within the scope of his agreement

Essex Public Medical Service

The report for 1938 shows that this service is making steady progress The number of subscribers has now risen to 21,000, an increase of nearly 2000 over 1937, and the increase would have been larger still but for the number of fourteen-year-old subscribers who came off the books owing to the extension of national health insurance. The great distress that is prevalent in parts of Essex owing to the slowing down in the building trade also led to many cancellations. The number of active medical members of the service is 305 No distinction is now made in rates of subscription between adults and children, the weekly payment, which includes drugs and administration, ranging from 4*d.* a week for one person to 1*s.* 3*d* a week for a family of six. The service has no difficulty in paying its way and showed a surplus of £650 for the year, most of which will be distributed to members as a bonus

A Record Quarter

During the first quarter of this year the number of prescriptions issued by insurance practitioners in London reached the record figure of 3,015,846, costing £101,661, as compared with 2,571,840, costing £87,091 in 1938 The increase was partly due to a rise of some 43,000 in the number of insured persons, but the average cost per person also rose from 11 20*d.* in 1938 to 12 78*d.*

PUBLIC HEALTH

Another Side of the Defence Programme

THE Prime Minister and the Minister of Labour have expressed natural pride in the results of the physical examination of the militia recruits. These suggest, no doubt, that our social and health services have been developing along sound lines, and are a testimony to the merits of preventive medicine, though the possible fallacies of this deduction are considered in a leading article on another page There is, however, another aspect of the problem. Medical practitioners are becoming increasingly conscious of the effects of the emotional side of life on physical and mental health. Anxiety states are becoming commoner in young people, and illness may sometimes be an unconscious escape. In other cases there are restlessness and irritability, if not actual misdemeanours, with unfortunate effects in and outside the home Some of this may be an inevitable result of the increased momentum of modern life, with its accompaniments World conditions also tend to increase any feeling of insecurity or fear that is present. Parents in the past have seldom been adequate guides to their children on the so-called facts of life, and today there is a changed relationship between them. Something has been gained by the change, but much has been lost, and helpful counsel has too often accompanied discipline in its flight. The freedom of modern youth is exercised in an atmosphere of sex stimulation greater than ever before, and though the course of the whole life is usually determined in the unstable years of adolescence any preparation and guidance for these critical years of adjustment have been almost left out of our educational system.

The deputation of youth leaders last month to the Minister of Health and the President of the Board of Education was anxious to see something more being done to give help and guidance, and to prevent the physical and nervous casualties which present conditions make only too easily. They were able to show that the years from 14 to 25, in addition to juvenile delinquency, produced most cases of illegitimacy and venereal disease It was further disclosed that of four million young people between the ages of 14 and 18 less than three-quarters of a million were within the influence and care of the youth organisations The deputation expressed a fear that emergency conditions might slacken self-discipline and self-control, and their plea was for the Government departments concerned with health and education to grapple with this part of a real defence programme. Sir Walter Langdon-Brown (chairman of the British Social Hygiene Council) and Dr. Vynne Borland (Society of Medical Officers of Health) spoke of the need for an adequate preparation for life This means instruction for parents, more and better biology in schools, and simple scientific and psychological information for adolescents about themselves and also concerning their responsibilities as future citizens and heads of families Where these things have been done their value has been proved. Local authorities can provide these services; some of them do, but many do not. Insurance committees can also help Government stimulation of local effort is desirable, but these services are being curtailed by lack of funds We trust the deputation was successful in convincing ministers that money so spent would be a defensive investment.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 24, 1939

Notifications.—The following cases of infectious disease were notified during the week: Smallpox, 0, scarlet fever, 1597; diphtheria, 783; enteric fever, 54 (29 "expected"); pneumonia (primary or influenzal), 520; puerperal pyrexia, 186; cerebrospinal fever, 20; acute poliomyelitis, 12; encephalitis lethargica, 3; dysentery, 43; ophthalmia neonatorum, 87. No case of cholera, plague or typhus fever was notified during the week.

Twenty cases of enteric fever were reported from the county of Glamorgan distributed thus: Rhondda 13, Pontypridd 4, Llantrisant and Llantwitfardre 2, Swansea 1 The other 34 cases were reported in ones or twos from 11 county boroughs, 2 metropolitan boroughs, 10 urban districts, 3 rural districts, and 1 port

The number of cases in the Infectious Hospitals of the London County Council on June 30 was 2847, which included: Scarlet fever, 665, diphtheria, 513 (carriers, 17), measles, 20; whooping-cough, 784; puerperal fever, 19 mothers (plus 12 babies), encephalitis lethargica, 305, poliomyelitis, 3 At St Margaret's Hospital there were 24 babies (plus 11 mothers) with ophthalmia neonatorum

Deaths—In 126 great towns, including London, there was no death from smallpox or enteric fever, 7 (0) from measles, 3 (0) from scarlet fever, 12 (3) from whooping-cough, 13 (1) from diphtheria, 35 (7) from diarrhœa and enteritis under two years, and 8 (1) from influenza. The figures in parentheses are those for London itself.

Stoke-on-Trent reported 4 fatal cases of measles, Birmingham 2 Fatal cases of diphtheria were scattered over 11 great towns, South Shields reporting 3 Southampton had 4 deaths from diarrhœa, Birmingham 3

The number of stillbirths notified during the week was 231 (corresponding to a rate of 34 per 1000 total births), including 38 in London.

LETTERS TO THE EDITOR

STAFF CONDITIONS IN THE HOTEL INDUSTRY

SIR,—As a student of occupational hygiene, and a firm believer in the need for every worker to have a proper holiday each year with pay, I have been increasingly concerned to find serious shortcomings in the conditions of employment in the hotel and catering trades These trades are the mainstay of the holidays the rest of us enjoy It is therefore disconcerting to find that not only do hotel workers have to rely on the uneven flow of tips in order to obtain a living wage but that the hours are often very long and proper time for recreation lacking

Your columns, Sir, may not be the place to discuss economic matters in detail, but I trust you will allow this problem to be ventilated as a public-health issue Holidays have important prophylactic and therapeutic value They lie at the root of much of the work of the national fitness movement The time has come to see that those who work at the task of giving to others health and vitality during the best parts of the year should not be left unconsidered They too should have light and air, good working conditions, proper pay and adequate holidays Their standards of living should not be dependent on gratuities and the whole question should be the subject of full investigation and public consideration at an early date If every doctor would make it a self imposed task to inquire about staff conditions in the hotels and boarding houses in which they stay this summer, I think many will have their eyes opened to matters which have for too long been taken for granted

It is only fair to say that management is not necessarily to blame for shortcomings Methods of taxation and rating, the absence of a proper code of hygiene enforceable equitably on all establishments and the unregulated demands of the public make it almost impossible for some establishments to survive com petition and at the same time give their staffs the conditions they would wish This is not a question for recrimination but mainly one for objective inquiry and common sense, fair and equitable regulations

I am, Sir, yours faithfully,

Beeston, Nottingham June 27 L P LOCKHART

AN ORTHOPÆDIC UNIT FOR CHINA

SIR,—During the past year the Chinese Red Cross has come to realise the importance of orthopædics in war surgery and has sent an appeal for help to the British Orthopædic Association We are asked to provide a relatively small (250 beds) teaching unit, to be established well behind the Chinese lines, and a surgical director whose business it will be to instruct Chinese surgeons in orthopædic surgery, so that they will then be able to deal more competently with the enormous numbers of wounded at other military and civilian hospitals The sum required is £3500—£10 for the provision of each bed, and £1000 for special equipment in the practice of orthopædic surgery

It is unusual for a small and purely scientific society like the British Orthopædic Association to undertake a responsibility of this kind, but the appeal is such that it cannot be refused. The members of the Association have already given over £1100 (the list of donations is below), but they cannot possibly subscribe the whole amount themselves We are therefore asking, in coöperation with the British Fund for the Relief of Distress in China, for the aid of the medical profession as a whole

These are difficult times, but there was never a period when it was so desirable to show that medicine is international in deeds as well as in words This country has given the world Sir Robert Jones, the greatest orthopædic surgeon of all time, and it is natural that another country, desperately in need of enlightenment in the treatment of limb and spinal injuries, should look to us It is proposed to call the surgeon who goes to China "The Robert Jones Emergency Relief Surgeon"

The urgency and the importance of this appeal cannot be denied, if generous support is immediately forthcoming it will be possible to dispatch a surgeon with little delay, as arrangements for the administration of the fund in China have just been completed

Donations may be sent to either of the undersigned and should be marked "orthopædic"

We are, Sir, yours faithfully,

NAUGHTON DUNN,
President British Orthopædic Association,
15, Calthorpe Road, Edgbaston,
Birmingham,

H GORDON THOMPSON,
Executive Secretary and Treasurer, British Fund for the Relief of Distress in China,
121, Westbourne Terrace, W 2

PS.—The following sums have been received from members of the Association whose names appear below two donations of 100 guineas, one of £50 14s 10d, six of £50, one of 25 guineas, eleven of £25, three of £20, one of 15 guineas, two of £15, one of 10 guineas, four of £10, nine of 5 guineas, three of £5, one of 4 guineas, four of 3 guineas, one of £3, seven of 2 guineas, and eleven of 1 guinea Total £1126 10s 10d

THE PROBLEM OF MEDICAL LITERATURE

SIR,—The suggestions outlined by Professor McDowall, Mr Lloyd, Mr Zachary Cope, and Mr Barnard indicate the need for a conference at which the problem may be fully discussed, both from the medical man's and the librarian's viewpoints Discussion should include the ideas of both the user and the administrator of the literature. I venture to add the following remarks —

(1) The need for the publication of a British journal abstracting medical literature is very real and the arrangement of this periodical might be based upon that of the *Quarterly Cumulative Index Medicus*, although more frequent publication is highly desirable

(2) Unofficial coöperation between librarians to persuade their committees to drop subscriptions to periodicals is most dangerous for the following reasons (*a*) journals duplicated in most libraries are those in most demand, and to expect to borrow them from another library for any length of time is fallacious, (*b*) when a research worker requires a book he usually wants it at once and cannot be expected to wait while the librarian sends to the nearest library stocking it, where it is quite possibly in use, and (*c*) a library cancelling the subscription

to a periodical cannot be sure that this will always be available at the library at present willing to lend it, and to make up sets by the purchase of back numbers is often extremely expensive.

(3) Most medical men belong to certain medical societies, and those in London have access to some of the largest collections of medical literature in existence. They cannot expect any one library to stock everything, and the existence of published catalogues of medical libraries and of joint catalogues makes the tracing of papers comparatively easy.

(4) Many libraries are most willing to borrow but not to lend, and this is often caused by the attitude of members of the staff who are very annoyed when a required volume is found to be on loan to another institution.

(5) The idea of a central library taking every periodical and the more expensive monographs is to be commended, and, if it could duplicate the stock so that a copy would be available for reference and another for loan its importance would be enhanced.

(6) Although many libraries will not lend their stock, few librarians will refuse to allow a person to consult the books under his care.

(7) The main problem appears to be a matter of finance. An abstracting journal would have to be promoted; abstractors and translators must be paid, and libraries are at present notoriously understaffed. The money will not be raised by cutting down subscriptions to periodicals; it would be better to increase present facilities by cooperation for the mutual loan of rare material and of reproductions of more modern papers by the photostat and microphotography. The interchange of duplicates and of unused material is also a source but little exploited at the moment, despite the fact that most libraries are cramped for space.

These are some of the points that would have to be considered in any attempt to solve the problem.

I am, Sir, yours faithfully,

JOHN L THORNTON,
Librarian

St Bartholomew's Hospital Medical College,
E C 1, July 3.

ERGOTAMINE TARTRATE IN MIGRAINE

SIR,—In my letter in THE LANCET of July 16, 1938, I endeavoured to dissipate the doubts as to the effect of continued treatment with ergotamine tartrate (Femergin Sandoz) expressed in communications I received from medical men all over the country, following the publication of my experience of this alkaloid in your issue of March 27, 1937. In this letter I stated that for over a year I had used the alkaloid prophylactically and had injected the contents of a 0 5 c cm ampoule (containing 0 375 mg. ergotamine tartrate) every night without ill effect of any kind thereby completely eliminating the morning headache that I had always experienced on awakening.

As another year has now elapsed, during which I have continued this practice without a day's intermission and again without the slightest ill effect, I feel that this somewhat unique experience should be recorded. With the exception of Macdonald Critchley, who has referred to two cases receiving 0 4 and 0 7 c cm femergin daily for two years and one year respectively (*Medical Annual*, 1939, p 336), none of the workers who have had extensive experience of the treatment (including such authorities as von Storch, O'Sullivan, Graham and Wolff) mention anything approaching so long a trial—i e., two to three injections a week for a year and a daily injection for the following two years. I would also like to record the case of a patient.

A lady of 74 had suffered all her life from a severe and incapacitating migraine, in which, as in my own case, the attacks steadily became more frequent as she grew older, until she was scarcely ever free At the time she began treatment with ergotamine in June, 1937, she was debilitated, could only partake of a very restricted diet and had lost a lot of weight. She received so much benefit, although only taking tablets orally with an occasional injection, that in March, 1938, she began having a 0 5 c cm. ampoule injected every night. This led to great improvement, but she was still not completely free from headaches As her attacks were much more severe than my own, I thought that a larger dose was indicated in her case, and in August last she began taking 1 c cm. regularly every night This proved effective and after a daily injection for 15 months she is much better in general health than she has been for years, is exceptionally active physically and mentally, has gained 14 lb. in weight, can eat anything, and is, as she says, "a new woman."

I think that the cases of this lady and myself are strong evidence that the fears expressed in regard to the danger of continued treatment are greatly exaggerated.

I am, Sir, yours faithfully,

Desford, Leicester, July 1 T. W. GORDON KELLY

RENAL IRRITATION DURING SULPHONAMIDE THERAPY

SIR,—In September, 1938, Robertson [1] reported a brisk hæmaturia which appeared on the third day of M. & B 693 treatment of a boy, aged 14, with pneumococcal meningitis, and lasted two days; he suggested that it was due to the drug In March, 1939, Adalja [2] reported a case of hæmaturia during treatment of a pneumonic patient with M. & B 693, the hæmaturia ceasing on withdrawal of the drug. Gross and Cooper [3] and Antopol and Robinson [4] simultaneously reported finding urinary calculi in rats, rabbits, and monkeys, after receiving the same drug. This seems to indicate renal damage, in which case the following facts may be of interest.

During the past few months 75 male patients with gonorrhœa have been treated with M. & B 693 or with Uleron at the V.D. clinic, Royal Victoria Hospital, Belfast Routine microscopical urinary examination revealed the presence of red blood cells in 35 (46 6 per cent) cases: 29 out of 65 treated with M. & B. 693, and 6 out of 10 treated with uleron. In the case of M & B 693, 26 of the patients showed the cells either during treatment (8 cases) or within the first five or six weeks following cessation of chemotherapy With uleron 5 cases demonstrated the phenomenon during chemotherapy and 1 within two or three weeks following the end of treatment In no case was the dose of either drug excessive, the maximal dose with M & B 693 being 29 5 g over a period of fourteen days, and with uleron 36 g given in three four-day "stosses," the "stosses" being separated by eight-day intervals In most of the cases treated with M & B. 693 dosage varied from 15 to 22 g over a period of seven to ten days

Trauma was a possible explanation in 6 cases, for the appearance of the red blood-cells followed within a short time after instrumentation, but in 5 of these red blood-cells were also found either before or months after mechanical interference. Most of the cases showed the cells on more than one occasion, and several were still exhibiting them on their default several weeks after cessation of chemotherapy

Except in 4 cases, the laboratory report was "nil or occasional red blood-cells" In the 4 exceptions

1 Robertson, K., *Lancet*, 1938, 2, 728
2 Adalja, K. V., *Brit med J* March 25, 1939, p 643
3 Gross, P., and Cooper, F B., *Ibid*, May 20, 1939, p 1055
4 Antopol, W., and Robinson, *Proc Soc exp Biol*, N Y 1939, 40, 428

a "moderate number of red blood cells" was found on one or more examinations Oxalate crystals were found in 3 instances, and casts but no red blood cells were reported in 1 case with M & B 693 Oxalate crystals but no red blood cells were found in 1 patient who had been treated with uleron In 2 cases red blood cells were also found before chemotherapy Red blood cells appeared in 1 case during a first course with M & B 693, but no reappearance was noted after a second exhibition of the drug In 1 case cells were found during a second but not during the first course of the drug In 1 no red blood cells were reported during two courses of M & B 693, but they were found on several occasions during and after subsequent treatment with uleron, and 1 case showed red blood cells after treatment with M & B 693 but has not so far had a repetition of the condition despite one five day 'store' of uleron He is still on treatment

Examinations of the concentrations of M & B 693 in the blood and urine were carried out by Werner's[5] method in 7 cases, and of these 4 showed a maximum of the free drug in the blood of over 4 mg per 100 c cm and 2 a maximum of over 6 mg per 100 c cm A urinary maximum of the free drug of over 170 mg per 100 c cm was found in 5 cases, 3 showing over 200 mg per 100 c cm In another case the 'combined' drug was almost four times as great as the amount of "free" throughout treatment, an unusual finding in my experience

As pointed out, the dosage in this series was small In view of the heavy dosage at present suggested by a number of workers, I feel that this preliminary report is justified

I am indebted to Dr J C Rankin and Dr H E Hall, of the V D clinic, Royal Victoria Hospital, Belfast, for permission to publish these reports, to them and to Prof E B C Mayrs, of the department of pharmacology in Queen's University, Belfast, for their helpful criticism and advice, and to Dr J Houston, of the department of pathology, Royal Victoria Hospital, for most of the microscopical urinary examinations

I am, Sir, yours faithfully,

J S McCANN

UNORTHODOX TERMINOLOGY

SIR,—I was almost "terrified" this morning, when by chance I read the comment of "Dr Pangloss" in THE LANCET, June 24, p 1462, on my article in the issue of June 17, p 1395 Of course I know that "terra" means "dry," because we have a river in Catalonia which is always dry, for which reason the Romans called it the 'Ter' "Terra" means dry and means "death," too, as opposed to "water" (wet), which means "life" This was known in ancient times and is the reason why the Egyptians, for instance, used the "rice test" to detect criminals, it was supposed that those who had committed a crime should be terrified (dry) and could not swallow the rice Everybody knows that fear compels the individual to drink to overcome his "dryness"

I admit that my etymology may be unorthodox, and I thank "Dr Pangloss" for his teaching, but, still, it seems to me easier to connect *terr* or with *terra* than *terr* or with *trem*-or

I am, Sir, yours faithfully,

E MIRA

Maudsley Hospital, Denmark Hill, S E 5 June 29

PRESENTATION TO SIR ROBERT KELLY

SIR,—A committee, consisting of representatives of the Liverpool Royal Infirmary and other teaching hospitals, Liverpool University, and of his old surgical registrars and house surgeons, has been formed to collect funds for the purpose of presenting Professor Kelly with his portrait, and in addition of perpetuating his name by a scholarship in association with surgical teaching or research at the University

The appeal is being circulated to members of the above institutions, but it is felt that other medical men might like to associate themselves with the presentation Subscriptions should be made payable to the University of Liverpool, and should be sent to the finance officer at the University

I am, Sir, yours faithfully,

HUGH REID,
Secretary to the Committee

Liverpool June 30

OBITUARY

WILLIAM MOSES FELDMAN

M D LOND, F R C P, F R S E

THERE can be few men who combined such a deep book learning of child hygiene with practical experience as Dr Feldman, who died suddenly on July 2, at the age of 58 He was born in Russia, the son of Israel Feldman, a merchant, and educated at the Jews' College and at the London Hospital, where he qualified in 1904 He went at once into general practice in the Whitechapel Road, where he remained all his life, at the same time doing non-resident appointments at the London Hospital Child welfare was his main interest from the first, and in 1907 he published his book on "The Child its Rearing, Development and Ailments," followed soon afterwards by his "Manual of Nursery Hygiene" He became physician to St Mary's Hospital for women and children and to the East End Dispensary At the same time mathematics was his hobby, and he applied it to such problems as calculating the number of capillaries in the human body and its surface area He found time too, to busy himself with social work, more particularly on behalf of the Jews, and he was a member of the Stepney borough council and of the council of the Society for the Study of Inebriety He lectured for the London county council on midwifery and hygiene and in 1924 he gave a Chadwick lecture on antenatal and postnatal child physiology, he also examined for the General Nursing Council He had a constant urge to write, his most ambitious work being his "Ante and Post natal Welfare," published in 1927 In this remarkable compilation he reviewed methods of promoting the well being of children from every angle—historical, literary, biological and practical, and such was his grasp of the subject that he made even the more technical aspects easily comprehensible

In 1913 Dr Feldman married his cousin Hilda Feldman They had no children

TRAINING FELLOWSHIP IN PSYCHOSOMATIC RESEARCH.—The Rockefeller Foundation has made available for three years from Sept 1 a training fellowship of the annual value of £150, which is tenable at the Tavistock Clinic Further particulars are given in our advertisement columns and application forms may be obtained from Dr A T M Wilson, Tavistock Clinic Malet Place, London, W C 1

Wellcome Historical Library

PARLIAMENTARY INTELLIGENCE

ON THE FLOOR OF THE HOUSE

By MEDICUS, M.P.

THE discussions in the House last week were for the most part on the Finance Bill, three days, the Armaments Profits Duty one day and unemployment for the wind-up of the week on Friday. The Minister gave statistics to show the increase of those registered as employed. The opposition pointed to the serious condition of the areas where unemployment reached a high percentage of the available labour. As one member said, "There is a total of 25,999 people in Durham county who have not worked for more than a year." It is very little help to these people to know that others are employed.

* * *

The question of unemployment must for certain statistical purposes and for the purpose of the unemployment insurance benefit be considered from the point of view of numbers But these numbers require careful interpretation if the effect on the body politic of the disease of unemployment is to be accurately diagnosed and adequately treated Long-term unemployment—as was brought out in the debate—produces "devastating physical effects" The director of education of Durham county has shown recently that 16 8 per cent of the secondary-school pupils in Durham are suffering from undernourishment and he suggests that "something should be done" to provide solid meals for those children A comparison between pupils in Durham and pupils in Surrey was interesting—the Durham (Spennymoor) pupils were about one year behind the Surrey (Surbiton) pupils in physique The medical officer concerned was quoted in the debate as saying, "In my opinion the returns are indicative of a deterioration in the nutrition of a proportion of the children formerly classified as normal. This deterioration has occurred in spite of the fact that the number of children receiving free milk in the secondary schools has increased each year since the scheme was inaugurated, and, as in the case of the elementary schools, I am disposed to recommend the provision of solid meals in the secondary schools"

Mr. Joseph Stewart, who dealt with this case, showed how Durham county had had to spend £63,000 on food for elementary-school children, £30,000 on liquid milk meals and £30,000 on milk for nursing and expectant mothers, while over a million and a half was spent (in 1938) on public assistance and over five million on unemployment benefit and allowances—yet with all this "our people in the special areas are deteriorating."

Another aspect of the same problem was brought out in the report of the Unemployment Assistance Board, where, in the introduction, Lord Rushcliffe, the chairman, calls "the most serious attention" to the effect of prolonged unemployment on 100,000 young men Mr. Arthur Henderson said that a visitor from another planet would find it difficult to understand why there should be any unemployment at all The potentialities of consumption were greater than those of production

Running through the debate was an expression of apprehension. If the numbers and conditions of unemployed are as they are today with all the boom demand for employment on armaments what will they be in the future when—at some time—the piling up of armaments ceases? What is to happen in a post-war or a post-peace world with production on a normal footing? Mr. Ernest Brown, the Minister of Labour with the famous voice, did his best to be cheerful and optimistic about it But the House was not really convinced despite the vote. The question still remains to be answered: "What is the disease of unemployment doing to the body of the nation?" The House did not answer the question Perhaps it is a question for a preventive social medicine service.

* * *

This week the Government are presenting a Milk Industry (No 2) Bill in place of the one which was introduced in November last and withdrawn because of opposition on the Government side The original bill contained 75 clauses and 8 schedules, the present one contains 10 clauses and 1 schedule The proposals for pasteurisation are dropped, but "consumers' committees" are to be brought into consultation with boards and other persons before prices and terms of sale of milk are settled And payments are to be made to milk producers who produce and sell accredited milk, standard milk, tuberculin-tested milk, certified milk or milk from an attested herd One proposal, in clause 2, provides for Government contributions to milk marketing board towards the supply of milk at reduced prices for consumption by school-children, expectant or nursing mothers or children under five A bill passed last year put a sum of a quarter of a million at the disposal of the Government to pay for milk for expectant or nursing mothers or children under five, but up to last month and presumably up to the present time none of that money had been spent because the Government did not make arrangements to pay for milk distribution. The House will certainly want to know whether the "provisions" of the bill will be purely "administrative" or whether, in the future, they will have a definite nutritive value

FROM THE PRESS GALLERY

Scottish Health Services

IN the House of Commons on July 4 Colonel COLVILLE, Secretary of State for Scotland, in introducing the vote for the Department of Health, said that with a net increase of over £270,000 on last year the total estimate was brought to over £4,000,000. Housing accounted for the greater part of the increase, but among the other items showing increases were the maternity services and the Highlands and Islands medical services. The items that showed the more important decreases come under the head of national health insurance, and these decreases were due partly to a windfall from the navy, army and air force insurance fund, and, in greater measure, to the lower rate of sickness among the general insured population in 1938. A new item was the grants to local authorities for cancer treatment, the beginning of what he hoped would be an effective aid in the fight against this disease.

The department was working at high pressure on emergency work of civil defence, including the organisation of the emergency hospital service and of medical, nursing, dental and other personnel, the approval of first-aid posts and ambulance schemes made by local authorities, the evacuation scheme and the provision of camps The financial provision for this work ran into millions.

There could be no doubt, said Colonel Colville, that the health and other social services were returning a substantial dividend in the form of improved health standards. In 1938 the general death-rate, the infant death-rate, and the tuberculosis death-

rate were all the lowest on record The infant death rates in Edinburgh, Dundee and Aberdeen were now less than half what they were at the beginning of the century School health records showed that, in height and weight and general vitality, the children at different ages were better physically than their predecessors In Glasgow the boys of thirteen were 7½ lb heavier and 2 in taller than the boys examined in 1920, the girls were 9 lb heavier and 2 in taller

In regard to the Maternity Services Act passed in 1937, the initial difficulties were now being overcome, and the act was being brought into operation in different parts of Scotland Schemes under the act were in operation in the areas of 14 local authorities, another 9 schemes had been approved and would come into operation shortly, and many of the schemes of the 30 remaining local authorities were at an advanced stage It was worth noting that for the first *time in history the population of Scotland* had reached the 5 million mark, according to the provisional estimate of the registrar general

The increasing numbers of old people partly explained the increased incidence of cancer Colonel Colville hoped to issue shortly a circular to local authorities on the Cancer Act, but the full operation of the act would depend on, among other things, exact knowledge of the existing facilities in Scotland, what developments were desirable, and where An expert advisory committee was at present considering these matters, and he hoped to have its report before the end of October

Workers in this field had been inspired by success in related fields Last year, for instance, recognition of the therapeutic value of the sulphanilamide compounds—including the well known M & B 693—opened up new vistas in the treatment of certain diseases that were the active concern of the health authorities These compounds had had marked success against puerperal fever, one of the main causes of maternal deaths, and there seemed to be good promise that in them a means of controlling the scourge of pneumonia had been found

The increase of £10,000 for the Highlands and Islands medical service brought the total under this head to £100,000—2½ times the original provision It was wanted mainly for assistance towards the cost of a new general hospital at Lerwick, Zetland, and additions to the general hospital at Stornoway in Lewis These two hospitals were essential links in the chain of medical services—doctors, nurses, hospitals, specialists, and so on—that now served admirably the Highlands and Islands of Scotland The air-ambulance service between the Western Isles and the *Renfrew* airport continued to prove a boon in urgent cases During 1938 over 30 patients were transported by air to hospital at Glasgow under the grant-assisted schemes of the county *councils of* Argyll and Inverness

About the hospital services of Scotland generally Colonel Colville said that there were still deficiencies, but schemes for repairing them were under way. These included a large new general and maternity hospital and a new fever hospital in Lanarkshire.

The number of persons coming within the scope of the national health insurance scheme increased in 1938 by nearly 200,000 and the expenditure on cash benefits per head declined from 4 *80d* in 1937 to 4 *10d* in 1938. The decline in that expenditure reflected a lower sickness rate, the average cost was the lowest since 1931 But influenza had been busy during the opening months of 1939, and sickness expenditure increased accordingly

A new scheme for milk at reduced prices to nursing an expectant mothers and children under five years of age had been started The intention of this scheme was that one pint of milk a day, free, or at a price not exceeding *2d* a pint, should be supplied He had brought this scheme to the notice of local authorities, and the reception had been favourable

Collections for Hospitals

In the House of Lords on July 4 Lord MACMILLAN moved an amendment to the Charitable Collections (Regulation) Bill, providing that where a police authority refused to grant a licence or revoked a licence which had been granted, the applicant or holder of the licence might appeal to the Home Secretary He said that it seemed ridiculous that a hospital, such as the Hospital for Sick Children in Great Ormond Street, which was supported by people in every part of England and many in Scotland, should have to obtain the authority of the police in every particular area where a collection was made For this hospital, which was to all intents and purposes a national charity, and for many other hospitals to have to get the necessary licences all over the country would be extremely hampering to their work.—The Marquess of ABERDEEN said that the joint committee had discussed the question of an appeal and had come to the conclusion that because of the difficulty of confining it to reputable cases of charity there ought to be no appeal The local police would know which were the reputable institutions in their district.—The amendment was withdrawn

Lord LUKE moved an amendment providing that the Home Secretary might exempt from the necessity of obtaining a police licence a person desirous of promoting collections for a voluntary hospital approved by the British Hospitals Association or by King Edward's Hospital Fund He said that the reason why the hospitals were not included in the favoured list of charities associated with the bill was because they did not beg nationally It was admitted that they served the community very well locally and in some instances did so throughout the country, but on the whole their service departments were usually better than their appeal sections, and the latter did not often reach from Land's End to John O'Groats In the past they had obtained support from an area, say, of 50 or even 100 miles around their hospitals, from which district they received the bulk of their patients, though in these days of motor accidents they might have patients from any part of the country Their area might include half a dozen, or even a dozen, police divisions and in each of these the favoured outside authorities would start with an advantage over the local hospital by having exemption The amendment would not put the local hospitals at the head of the favoured list of charities, it would only put them on a level and that after they had been thoroughly approved by one of the two central hospital bodies.—The Earl of COURTOWN said that the proposal would give undue advantage to a voluntary and non-elected association The application of a local hospital which did not belong to that association for a licence to make a collection might be regarded with some doubt by the police The joint committee had fully considered the matter and had decided that it was not necessary to include voluntary hospitals.—Viscount BRIDPORT said that the Government could not agree with the amendment The trouble involved in applying to several police authorities in cases where a hospital covered a wide area would not be great.—The amendment was negatived

The Milk Industry

In the House of Commons on June 29 Sir R DORMAN SMITH, Minister of Agriculture, presented the Milk Industry (No 2) Bill, a measure "to authorise certain payments out of the Exchequer to milk marketing boards in respect of certain milk, to extend the powers and vary the duties of such boards as to the making of payments or allowances to producers of milk and in connection with approved arrangements for the sale of milk at reduced prices, and as to the manner in which moneys paid to the boards from the Exchequer are to be dealt with, and to extend the functions of consumers' com-

mittees in relation to milk marketing schemes and milk product marketing schemes and milk product development schemes." The bill was read a first time.

QUESTION TIME

JUNE 28–JULY 5

Medical Examination of Militiamen

Mr. PARKER asked the Minister of Labour whether he could give any explanation of the great divergence between the results of medical examinations for the Regular Army, the Royal Air Force, and the Militia.—Mr ERNEST BROWN replied: The medical examinations for the regular forces have in view the requirements of the particular units in which the men wish to enlist, and cover a much wider age-range than that for the militia. Moreover, it is a common practice for an intending recruit who is rejected at one centre to try again at other centres or for other units and in this way the figure for rejections is to some degree inflated For these reasons the real divergence between the results for the regular forces and those for the militia is considerably less than that represented by the crude figures

Sir V. WARRENDER explained that in the event of a militiaman wishing to transfer to the Regular Army on completion of his service, he would again be medically examined to determine his fitness for the particular branch of the service to which he wished to transfer.

Answering three inquiries Mr ERNEST BROWN said he would have a copy of the instructions issued to the medical boards placed in the library.

Mr. MATHERS: Will it not be possible for more publicity to be given to these instructions?—Mr. BROWN The instructions are long and elaborate and have been drawn up with great care in consultation with a number of experts.

Dr. SUMMERSKILL asked whether a militiaman who had an unsatisfactory medical history and who was dissatisfied with the decision of the examining doctor was given the right to appeal for a second opinion from a specialist.—Mr. BROWN replied: The decisions of the medical boards are final, but arrangements are made for men to be referred to consultants for report when the boards are in doubt

Dr SUMMERSKILL: Is the right hon gentleman aware that many members on this side of the House have cases sent to them day after day of men who have been certified as suffering from a certain complaint but are now passed fit for service?—Mr BROWN: I hope that hon. members will send them on to me. The thing that has struck me for the last fortnight is the very small number of letters I have had on this matter

Physical Defects in Militiamen

Mr. JOHN MORGAN asked the Secretary of State for War if any special steps would be taken to remedy admitted physical defects in militiamen, accepted for other grades than grade I, while undergoing their period of military service.—Sir V. WARRENDER: Medical and surgical treatment will be available as for regular soldiers Minor physical defects will be noted on medical examination and by staff instructors in physical training. Those requiring remedial treatment by physical-training methods will be divided into groups according to their defects, and remedial treatment will be carried out under the supervision of staff instructors

Unemployed Persons and Physical Defects

Mr DAVID ADAMS asked the Minister of Labour how many men in receipt of Unemployment Assistance Board allowances were estimated to be unable to obtain work owing to remediable physical defects, and as treatment of eyes and teeth frequently could not be obtained through existing medical services he would take immediate steps, in conjunction with the Ministry of Health, to extend the public-health services in this direction.—Mr. ERNEST BROWN replied: I regret that more precise information than that given on pages 46–47 of the board's annual report for 1938 is not available I am already in communication with the Minister of Health on the matter raised in the second part of the question

Health Insurance Handbooks

Mr LOGAN asked the Minister of Health when he intended to issue an up-to-date consolidation of the National Health Insurance Acts; and if it was intended also to issue an approved societies' handbook.—Mr ELLIOT replied: I understand the reference in the first part of the question to be to the projected volume containing the consolidated National Health Insurance Acts and the regulations made thereunder. While some progress is being made in the preparation of this volume, and also of a revised edition of the Approved Societies' Handbook, pressure of other urgent work in my department has delayed their completion I hope that it may be found possible to issue the former volume within the next few months, but I am afraid that I cannot promise an early issue of the latter.

Expectant Mother's Choice of Doctor

Mr. GORDON MACDONALD asked the Minister of Health whether, as it was possible for circular 1705, sent out by his department, to so limit the choice of an expectant mother as to prevent her from having the services of her family doctor should she so desire, he would so modify the circular as to do away with such a hardship.—Mr BERNAYS replied: The circular does not impose or purport to impose such a limitation as is suggested in the question. The procedure suggested in the circular contemplates that ordinarily some practitioner on the list prepared by the local supervising authority will be acceptable to the expectant mother, but the circular makes it clear that where this is not the case and the expectant mother desires the services of some other duly qualified medical practitioner, this practitioner should be called in by the midwife.

Lancashire Advisory Committee

Mr. GORDON MACDONALD asked the Minister of Health the names of the advisory committee for the area of the Lancashire county council, set up in consequence of the same circular; and what consultations took place prior to the setting up of the committee.—Mr. BERNAYS replied: I am informed by the county council that the committee is composed as follows: Chairman: Dr Hall (C.M.O.) Obstetric consultants: Prof Leyland Robinson and Professor Dougal. General practitioners: Dr. Marsh and Dr. Winstanley Before making these appointments consultation took place, as suggested in the circular, with the organisations of medical practitioners which appeared to the county council effectively to represent the opinions of practitioners in the county. The President of the Royal College of Obstetricians and Gynæcologists was approached with regard to the appointment of the two obstetric consultants, and the general practitioners and their deputies were nominated for appointment by the Lancashire and Cheshire branch of the British Medical Association.

Rheumatism Eligible for Additional Benefit

Major CARVER asked the Minister of Health whether, in view of the serious incidence of rheumatism among insured persons, he would cause treatment at recognised British spas, given under medical recommendation, to rank for payment in whole or in part by approved societies where such were able to give additional benefit, No. 16, payment to approved charitable institutions in respect of any treatment of members required for the prevention or cure of disease provided under the third schedule of the National Health Insurance Act, 1936.—Mr. ELLIOT replied: I am prepared to consider the granting of approval for the purposes of additional benefit No 16 to any charitable institution which satisfies me that it has available diagnostic and other facilities of a high standard for the treatment of rheumatism I am not, however, at present satisfied that there is a sufficient case for the extension of the benefit to cover treatment at a spa otherwise than in an approved charitable institution

Ice-cream

Brigadier-General CLIFTON BROWN asked the Minister of Health whether he was aware that a considerable

amount of ice cream was made without cream or milk, and if he would bring in legislation to compel ice-cream makers to state the quantity and quality of milk used in ice creams they sold to the public—Mr ELLIOT replied I am aware that some frozen mixtures sold as ices or ice cream may contain little or no cream or milk. The Food and Drugs Act, 1938, which comes into operation on Oct 1, will give me increased powers for making regulations governing the composition of food and kindred matters, and I am considering the question of making regulations as to ice cream

Brigadier General BROWN Does not my right hon. friend think that the time has come when a statutory standard should apply to all ice cream sold; and will he make regulations to that effect?—Mr ELLIOT I will take these points into consideration

Sir PERCY HARRIS Have not the local authorities power to make by laws to regulate the sale of ice cream?—Mr ELLIOT I am not sure how far their powers go, but the new act will certainly give greater powers to the central department

Objection to Vaccination

Miss RATHBONE asked the Minister of Health whether he was aware that a statutory declaration of conscientious objection to vaccination made by the wife of a labourer in the Royal Arsenal, Woolwich, on behalf of her child, was recently refused by the vaccination officer of the Metropolitan borough of Woolwich on the ground that only the declaration of the father of the child could be accepted, he having its legal custody, that in this case the father was prevented from making a declaration owing to his hours of work being from 8 20 A.M. to 6 P.M., and that in many other cases the father might be prevented by illness, mental disability, or temporary absence from a home, and whether he would consider making such a change in the regulations as would enable the mother to make the declaration.—Mr ELLIOT replied My attention has not previously been drawn to this case The statutory declaration may be made before either a commissioner for oaths or a justice of the peace at any time I cannot, therefore, accept the contention that the father concerned was prevented from making such a declaration because of his hours of work I do not consider it necessary to propose the amendment of the law which the hon member suggests

Miss RATHBONE Is the right hon gentleman aware that this refusal to acknowledge the statutory declaration of the mother is not only practically inconvenient in many cases but is an insult to the mother and is quite inconsistent with the spirit of the declaration and of the Custody of children Act, and will not the Government consider taking action if necessary in the way of legislation to give equal rights to the father and mother in this matter?

Advertisements in Stamp Books

Sir FRANCIS FREMANTLE asked the Postmaster General if his attention had been drawn to two advertisements in current issues of 5s books of stamps, one headed trusses abolished, and the other claiming immediate results from an advertised remedy for bladder and other complaints, and whether he would take action to prevent Government publications from being used as a medium for such advertisements.—Mr MABANT, Assistant Postmaster General replied The policy of the Post Office is to exclude advertisements of medicines covered by paragraph 58 (2) of the report of the Select Committee on Patent Medicines 1914 The two advertisements referred to by my hon friend do not contravene the terms of this paragraph My right hon friend is looking further into the policy of the Post Office in this matter

Betting and Research

Replying to Sir THOMAS MOORE, Mr PEAKE, under-secretary, Home Office, stated that he was informed by the Racecourse Betting Control Board that from the surplus in the totalisator fund at Dec 31, 1938, £4500 had been allocated towards the advancement and encouragement of veterinary science and education The £1600 granted to the Agricultural Research Council towards the cost of investigation into the various diseases and disorders of horses would be applied in assisting inter alia research work at the Moredun Institution and the Royal (Dick) Veterinary College, Edinburgh £750 was granted to the building fund of the Royal (Dick) Veterinary College, Edinburgh £500 was granted to the Glasgow Veterinary College towards the cost of microscopes

Part II.—J C Birchall C Coleiro, H D Collins, F C R Couper, J N Das Beryl Edgecombe, Ivy F Fallon Elsie G Hughes J Leiper F T Madge, F H Moore, and Mofia Murray

D T H

J M Caldwell, S G Cowper L G Fiddey, W H R Jamieson K Nadarajah and T S Outerbridge

On July 1 the honorary degree of master of orthopaedic surgery was conferred on Mr H V T Fairbank

University of Sheffield

On July 1 the honorary degree of D Sc was conferred on Dr Miles Phillips emeritus professor of obstetrics and gynaecology in the university

University of Manchester

Dr J N Marshall Chalmers has been appointed assistant director of the laboratory of clinical investigation and research

Dr. W. E. St. Lawrence Finny has been elected a vice-president of the British Archæological Association.

Volunteer Blood-donors

Those who wish to volunteer as blood-donors in wartime may obtain the address of the centre in their district and other particulars by telephoning Central 8691 between 9 30 A.M and 9 30 P.M

University of Bristol

At recent examinations the following candidates were successful :—

M D

Constance I Ham

FINAL EXAMINATION FOR M B , CH B

Dorothy M. Shotton and C A St. Hill (with second-class honours); Dorothy M Ayre, P A Bennett, A A. K. Datta, Marjorie O Dunster, J L Emery, Emily G Hamlyn, Betty F. Hannaford, F R Hurford, N E Melling, Jeannette D Shed, S J Silvey, P. R H Slade, Sylvia E Smith, and T H. White

FINAL EXAMINATION FOR B D S

G H Bell, J E H Bell, J. F Blenkinsop, R J Gething, A A Grant, and D R Stevens

FINAL EXAMINATION FOR L D S

K A Gordon-Ralph, G H Hudson, E. L. Manton, R H G Sims, Mary E Thomas, May A Trump, L N Weale, H D Williams, and E S Wolfson

In dental surgery, completing examination: F W. Clift.

Dr. Ernst Philipp has obtained the degree of M D.

Dr Hilda Dutton has been appointed medical officer for the examination of women students and Dr. R G. Cookson medical officer for the examination of men students

University of Edinburgh

In 1926 on the recommendation of a special committee which had been set up by the university court a department of physical training was started in the university Colonel Ronald Campbell was appointed director and was asked to organise and develop athletic activities and physical culture of the students It has now been decided to institute a certificate of physical ability for men students who undergo successfully a progressive course of training extending over two consecutive sessions. At present there is no similar graded course for women but it is stated that "attention will be turned to this at an early date"

Royal College of Surgeons of Edinburgh

At recent examinations the following candidates were successful .—

L D S

W. W Brown, W J M Gillies, T D Grandison, Michael Lipman, John Provan, Winifred G Sivewright, E F Stonehouse, A M Sutherland, William Walker, and William Waterston

University of Glasgow

On June 30 the following degrees were conferred —

M D—J D P Graham (with high commendation), J. A. Crocket and T R Pahwa * (with commendation), F W. Bunting, J M Henderson, Alexander Lyall, and A M Steel.

* In absentia

Royal Faculty of Physicians and Surgeons of Glasgow

At a meeting of the faculty held on July 3, with Dr. John Henderson, the president, in the chair, the following were admitted to the fellowship .—

Habibud-Din Ahmed (London); William Ferguson Anderson (Whitecraigs), Tom Osborne Howie (Glasgow); Velu Pillai Kumara Pillai (India); Alfred Sands Rogen (Glasgow); Bhupendra Nath Sur (Edinburgh); and Abu Khaled Muhammad Abdul Wahed (Edinburgh)

University of Aberdeen

During the annual conference of the British Medical Association which is being held at Aberdeen from July 21 to 28, the honorary degree of LL D. will be conferred on the following :—

Dr H G Dain, chairman of the representative body of the association, Dr Thomas Fraser, president-elect of the association and consultant physician to the Aberdeen Royal Infirmary, Sir James Elliott, F R.A C S, honorary consultant surgeon to Wellington Hospital and editor of the *New Zealand Medical Journal*, and Dr Einar Meulengracht, professor of clinical medicine in the University of Copenhagen

The A W. Garden fellowship in ophthalmology and pathology has been awarded to Dr. D. F. Ritchie.

University of St. Andrews

On June 30 the following degrees and diplomas were conferred —

D Sc.—J D Robertson, M D

M.B , Ch B—B S Tulloch (with distinction), Winifred I MacNicol, A J M Cathro, W J McGinness, and Peter Kinnear (with commendation), R M Bell, J M Berry, J M Black, K G Broadbent, J. S Brunton, John Cameron, Elizabeth P Dodds, J. M. Duncan, A C Fraser, Elizabeth N Harrison, M C Hodgson, W F E Immelman, R. S Kennedy, R T Kiddie, Douglas Latto, H R Lillie, A R T Lundie, Elizabeth T MacDougall, E G McPherson, D J Macrae, Charles Milne, D S Milne, Freda C J Nicoll, R A Philp, D V. Porter, G H. Rea, G. W. Taylor, Kathleen S Turner, W H. Whyment, J S. Young, and John Young

B D S—I M B Allan, E A Haxton, R S Henderson, J L Hutton, and R P McGlynn

Diploma in Dental Surgery.—R. P Edwards, W R D Fraser, K G Galloway, D M Lawson, G M Lawson, G D McPherson, William Malcolm, and R R M. Wilson

D P H—W B Clark, C R Henderson, W M Jamieson, and William Sharpe.

Diploma in Public Dentistry—D. A. Henderson, Isabel S Powrie, W M Ross, and Robert Whyte

National University of Ireland

At recent examinations at University College, Cork, the following candidates were successful —

M D

V J. Dillon, William Kearney, J P. Morehan, and P F O'Connor

FINAL EXAMINATION FOR M B , B CH , B A O

M F McMahon and D J O'Callaghan (with first class honours), E A Scher, F H Cross, Madeline M Horgan, W F M. Fitzgerald, and M J Murphy (with second-class honours), G N Dalton, Anna T Gallagher, T G Galvin, D M Kelleher, Timothy Kelleher, Maev Kennedy, D J K McCarthy, P N Murphy, St J G O'Connell, T J O'Connor, J F O'Donovan, D A O'Sullivan, and Beatrice G Simmelkiar

Part I—T. F Coleman, J J. Hennessy, J. P Kenefick, M.S. Murphy, P. J Murphy, W P Navin, Mary L Neville, J S O'Dwyer, M G O'Mahony, John O'Regan, and P J O'Sullivan.

Part II—Matthew Bennett, J A Desmond, Diarmuid Herlihy, Thomas McCracken, and J A A Ryan

King's College, London

Dr D. B Taylor has been appointed lecturer in physiology at the college

French Decoration

The French government have conferred the order of palmes d'Officier d'Académie on Dr G. Gregory Kayne

Welsh National School of Medicine

Dr F R Magarey and Dr. H. D. Davies have been appointed demonstrators in the department of pathology and bacteriology Dr T. E D Beavan and Dr. Emily Williams have been appointed junior assistants in the medical unit.

Harveian Society of London

The summer meeting of this society will be held at the Associated British Picture Corporation, Elstree, on Saturday, July 15 Members of the society and their friends should meet inside the gate of the corporation between 2 45 and 3 P.M.

Social Hygiene Congress

The ninth Imperial Social Hygiene Congress will be held at B M A House, Tavistock Square, London, W.C.1, from July 10 to 14, under the presidency of Mr L S. Amery, M P Lord Horder will preside over a conference on social and economic barriers to marriage Dr Letitia Fairfield and Dr Socrates Noronha (Bombay) will speak in a discussion on medical and social coöperation; and Sir Arthur MacNalty will take the chair at a session devoted to technical, medical and administrative aspects of venereal disease at which Colonel L W. Harrison, M.B , and Dr. R. C L Batchelor will read papers Dr Ernest Prebble and Dr Gordon Bates, general director of the Health League of Canada, will discuss how to ascertain the incidence of venereal disease in a community An all day session will be given up to a conference on overseas nursing Dr A Cavaillon, inspector-general of the French ministry of public health, will read a paper on social service in the anti-venereal campaign Medical delegates are to visit the L C C Whitechapel clinic. Further information may be had from the secretary of the British Social Hygiene Council, Tavistock House South, Tavistock Square, London, W.C 1.

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1 Wimpole Street, W 1

TUESDAY

Psychiatry.—8.30 P.M. Dr C Killick Millard and Dr Letitia Fairfield Euthanasia and the Psychoses

ROYAL MEDICO PSYCHOLOGICAL ASSOCIATION

WEDNESDAY.—10 A.M. (Royal Pavilion, Brighton) annual meeting 2.30 P.M. Dr A Helen Boyle Watchman What of the Night? (Presidential address)

THURSDAY.—10 A.M. (Brighton County Borough Mental Hospital, Haywards Heath). Dr W J T Kimber Dr Lamorna Hingston Dr Twiston Davies Dr James Flind Dr Noel Harris Sir Hubert Bond Early Treatment for Mental and Nervous Disorders 2.30 P.M. Dr F A Carmichael, Mr G D Greville and Mr S G Tudor Jones Dr D J Watterson Symposium on Epilepsy

FRIDAY.—9.45 A.M. (Royal Pavilion) Dr A Meyer Mr W Grey Walter, Mr Norman Dott, and Prof F L Golla Symposium on Epilepsy 2.15 P.M. Dr J Taylor Box Dr G E Graves Peirce, Dr W McCartan and Dr J Carson Dr Guy Millman, Dr I Frost Symposium on Epilepsy (contd)

PADDINGTON MEDICAL SOCIETY

THURSDAY.—3 P.M. Visit to the Metropolitan Water Board, Kempton Park (Hanworth Road, Sunbury)

SOCIETY FOR THE STUDY OF INEBRIETY

TUESDAY.—4 P.M. (11, Chandos Street, W 1) Dr W Norwood East The Problem of Alcohol and Drug addiction in Relation to Crime

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane Road W 12

TUESDAY.—4.30 P.M. Sir Arthur Hall Meningitis and Acute Infections of the Central Nervous System

WEDNESDAY.—Noon clinical and pathological conference (medical) 3 P.M. clinical and pathological conference (surgical)

THURSDAY.—2.15 P.M. Dr Duncan White radiological demonstration 3.30 P.M. Dr A A Moncrieff Hygiene of the Newborn Child

FRIDAY.—2 P.M. clinical and pathological conference (obstetrics and gynæcology) 3.30 P.M. Mr J R Hume Hernia and Its Treatment

Daily, 10 A.M. to 4 P.M., medical clinics surgical clinics and operations, obstetrical and gynæcological clinics and operations

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, W C 1

THURSDAY.—2 P.M. Dr Donald Paterson The Leukæmias 3 P.M. Dr R. Bonham-Carter The Early Recognition of Infectious Fevers

Outpatient clinics daily at 10 A.M. and ward visits at 2 P.M.

ST GEORGE'S HOSPITAL, S W 1

THURSDAY.—5 P.M. Dr Anthony Feiling neurological demonstration

WESTMINSTER HOSPITAL Horseferry Road S W 1

TUESDAY.—5 P.M. demonstration of cases of Findlay's disease and of cerebral tumour

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION 1 Wimpole Street W 1

MONDAY to SUNDAY.—ALL SAINTS HOSPITAL, Central Street S.E.11 afternoon course in urology.—LONDON CHEST HOSPITAL, Victoria Park E 2, sat and Sun course in diseases of the heart and lungs

SOUTH WESTLONDON POST-GRADUATE ASSOCIATION

WEDNESDAY.—4 P.M. (St James's Hospital Ousley Road, S W 12) Dr C J Lakin demonstration of medical cases

NOTES, COMMENTS, AND ABSTRACTS

MEDICAL ASPECTS OF THE NEW CHINA-BURMA ROUTE*

BY R. C. ROBERTSON, M C , M.D. Glasg , M.R.C.P.E , D.P.H.

HEAD OF THE DIVISION OF PATHOLOGY AND SCIENCES, LESTER INSTITUTE OF MEDICAL RESEARCH, SHANGHAI , COMMISSIONER, LEAGUE OF NATIONS ANTI-EPIDEMIC UNIT NO 2 FOR SERVICE IN CHINA

THE League of Nations Epidemic Commission to China has specially entrusted me with the task of surveying the region extending from Kunming to the Burma frontier with a view to elaborating remedial measures and to advising the Chinese government about the control of epidemics

The opening of the China-Burma highway marks a new epoch in means of communication in the Far East and is of interest to epidemiologists in that India and China will be in closer contact, with an increasing risk of the transfer of epidemic diseases from one country to the other. There is reason to believe that cholera has been carried over the mountainous border from Burma into Siam on several occasions and has swept down the valleys towards the sea. Plague has visited Yunnan province periodically during the past centuries, having been imported by caravans from Tibet or from Burma. In 1866 it ravaged Yunnanfu During the last few decades plague has been quiescent, but the province can easily be reinfected, especially now that motor transport is available Plague-infected rats might easily be carried in cargo coming into China by the new highway. The Chinese government is aware of this danger and is about to establish health stations at important points.

PRESENT STATE OF CHINESE TRADE ROUTES

The importance of this new entrance to China cannot be exaggerated in view of the present situation which has developed out of the Sino-Japanese hostilities. Many of China's trade routes have been strangled The lines of communication from the great seaports of Shanghai and Hong-Kong have been completely disrupted The worst blow followed the fall of Canton, when not only was Hong-Kong rendered impotent as a source of supply but the railway line from Canton to Hunan and the north was effectively blocked More important still, the great river systems with the West and Pearl rivers are no longer free to transport cargoes to Kwangtung and Kwangsi The Yangtze river is effectively blocked as a trade route from Shanghai to unoccupied China Even local traffic above Hankow is at a complete standstill owing to the fact that the junction with the Tung Ting lake and the Siang river is the scene of warfare This paralyses river communications with Hunan province Changsha, once one of the busiest ports in the interior, has been destroyed by fire and has no outlet by river There is still a railway from Changsha to Hengyang and thence to Kweilin in Kwangsi but no link with the coast and the outside world The fall of Nanchang has now cut off the Chekiang railway, by which the port of Wenchow could be reached by a circuitous route. The Japanese navy has rendered the ports of Kwangchowwan (Fort- Bayard) and Pakhoi useless as a means of entry to the country.

The only deep-sea port at present available for the unloading of cargoes for China is Haiphong, in French Indo-China The French railway from Haiphong to Yunnanfu is a metre-gauge line which passes over very mountainous country with severe gradients There is a very limited rolling stock, and the line can handle only a small fraction of China's wanted imports; it cannot even deal with the unloaded cargo now congesting Haiphong docks. The French, at the request of the Japanese, have ceased to allow munitions to be transported on this line into China There is no direct highway from French Indo-China to Yunnan province; the sole motor highway by which China can be reached is a narrow tortuous road entering Kwangsi province near Lungchow This road passes Nanning, which is not far from the coast and is liable to be interrupted by a landing at Pakhoi at any time. The Nanning route is chiefly used for motor-lorry transport and the importation of new motor vehicles The only other ways of bringing supplies into unoccupied China are by a northern route through Soviet Russia and by the new Burma-Yunnan highway.

NEW CHINESE HIGHWAY

The British have always realised that a railway from Burma through Yunnan to Szechwan would benefit imperial trade, and that the port of Rangoon could become the starting-point for a connexion between the two great waterways, the Irrawaddy and the Yangtze. The railway from Rangoon to Mandalay had been extended to Bhamo, on the Irrawaddy river, and to Lashio, not far from the Yunnan border, at the end of last century (see the accompanying map) The Chinese are now constructing the new railway which will eventually connect Lashio with Kunming. This railway misses some of the difficult country which a connexion with Bhamo would involve, but it has to cross the valleys of the Salween and Mekong rivers The natural obstacles are tremendous, and it will be several years before the railway is finished; but the highway has already been completed in a remarkably short time by 200 engineers and 160,000 men (mostly conscript labourers) and lorries carry munitions for China's defence along it daily.

The mortality among the workmen on this road was very great, especially during the construction of the Burmese sections from Lashio to Anting (see map) where the route passes through some of the worst malaria districts of the world. No accurate estimate of the ravages of malaria can be made, for no organised medical service existed during the construction of the highway The government highway bureau employed a few doctors during the autumn of 1938 and distributed quinine to the sufferers, but reports are still coming in of many fatalities, especially in the districts near Mongshih, where malignant tertian malaria is rife

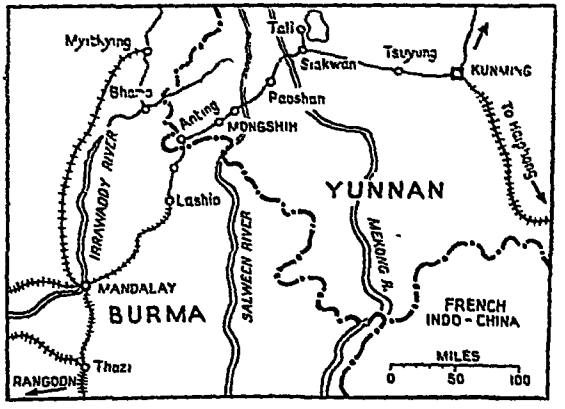
MALARIA IN YUNNAN

The valleys of the great rivers which flow southward through Yunnan province have always shown a heavy incidence of malignant malaria These rivers are the upper waters of the Red, Mekong, and Salween rivers Malaria is not so prevalent in the higher altitudes. Kunming is relatively free, except for a few months after the rainy season, when mosquitoes

* This paper has been abbreviated for publication, and a proof has not been submitted to the author

breed in temporary pools. During the greater part of the year the climate of the Yunnan Plateau is dry and not favourable to the breeding of mosquitoes.

A very different situation exists in the valleys towards the south and western parts of the province, where an annual rainfall of about 120 in. is common and malaria is endemic to a disastrous extent. It is very probable that within recent years the disease has become much worse owing to improved communications. For instance before the construction of the railway line from French Indo-China to Yunnan the city of Szemao in the southern part of the province was a flourishing centre with 160,000 inhabitants. Although this city is well away from the line and can only be reached by mule tracks or motor-car, it has been undoubtedly affected by the change of population during the last twenty years. Owing to the ravages of malaria the number of inhabitants has been reduced to 50,000. Many other centres have likewise been affected. The construction of the French railway is said to have taken a terrible toll of life the chief mortality being from *malaria*.



ANTI-MALARIA MEASURES

The chief danger of malaria along the new highway lies at present on the western portion of the route, where the disease is endemic among the inhabitants of all the towns and villages west of Paoshan (see map). Travellers along the highway, the drivers of the thousands of trucks which are beginning to use the road, are all exposed to infection if they stop in the villages, where up to now there is no sanitary control. The measures which are being instituted include the placing of mobile anti-malaria units supported by the League of Nations in the towns where malaria is endemic, intensive treatment of malaria patients with quinine, the supply of quinine as a prophylactic to travellers, the establishment by the National Health Administration of the Chinese government of general medical clinics, one to every 100 km., and the investigation of the local anophelines by the League of Nations Kunming Burma epidemiological survey unit.

In the immediate future it is hoped to improve the sanitation round hotels used by travellers, bus stations, and the local health-centres by drainage schemes and screening. To control malaria among the workers on the new railway it is hoped to establish anti-malaria clinics at the most useful points. Malaria cannot be controlled along this line with the efficiency with which it has been controlled in the Panama canal zone. The cost is prohibitive in China, and, to prevent a great wastage of human life, the funds must be supplied from outside China. The League of Nations is supplying quinine for the treatment of malaria patients in this region but much more is needed. Contributions of quinine from the governments of neighbouring and other countries would be a most useful way of helping to render healthier this important international trade route.

GOITRE

There is an extremely high incidence of goitre in Yunnan province together with obvious symptoms of cretinism, especially along the new highway. In some gangs of men and women working on the road the incidence of goitre is 60 per cent. It is not noticed in the children.

It is generally admitted that the addition of iodine to the diet even in very small quantities is sufficient to prevent further development of this condition but iodine is very deficient in these parts, not only in the salt but also in the vegetation. This is probably due to the geological conditions of the area for the salt which comes from the Yunnan mines is deficient in iodine. This is not the case with the mines of Szechwan. Normally some 70 per cent. of the salt needs of China are supplied with sea salt, which contains an adequate amount of iodine. The Japanese military occupation has cut off the hinterland of China from its coastal supply, and the deprivation of the normal sources of salt is one of the greatest hardships. To make up for this cutting off of the normal supply of sea salt the salt wells of China are being increasingly exploited and can probably supply the amount of sodium chloride needed but not a sufficiency of iodine.

Large areas of unoccupied China are now being supplied with this iodine free salt from the Yunnan mines, and the consequences of a deficiency of iodine are bound to become manifest particularly if hostilities are prolonged. In Yunnan province the typical area of production is the Hoching salt wells, where the brine is pumped out through bamboo pipes to vats and there boiled down. This has up to now been very largely a "cottage industry." The vats are in small houses, and each family controls and operates only a few vats. The output however, is carefully recorded by the Salt Administration. The salt crystallised is then transported to the main market in Kunming. The output from this district amounts to some 7530 tons a year. To provide adequate iodine content in the salt requires the addition of about 5 mg. of potassium or sodium iodide to each kg. of common salt.

Another way of supplying enough iodine in the ordinary diet is to use edible seaweed. The iodine in seaweed is said to be a hundred times more active than in potassium iodide. The daily need is less than 0·01 mg. of iodine a head (von Fellenberg's estimate

is only 0·014 mg.) It is recommended that a small amount of edible seaweed (about 10 g.) should be included in the diet twice a month At the moment it is very difficult to import seaweed to the goitre districts, but some of it reaches Kunming by the Indo-China railway. The inhabitants of Kunming are not heavily affected by endemic goitre, although the villages in the surrounding districts produce many sufferers.

While the question of supplementing the crude native salt with iodides is being considered, immediate steps have been taken to give a weekly dose of 1–2 mg of iodine in the form of potassium iodide to school-children and students in universities and other institutions where the personnel is under control or discipline It remains to be seen if, in the absence of preventive measures, the immigrants recently arrived from other provinces or from the war-stricken zones will acquire enlarged thyroids when they reside in goitre districts

OPIUM

The smoking of opium is very prevalent in Yunnan, where the drug is cheap and easily obtained Moderate addicts do not seem to have their health noticeably affected The question of control is at the moment outside the scope of the practical sanitarian. One can but hope that in due course the government will take the matter up energetically as in other provinces, particularly Kwangsi, during past years Yunnan may be said to have long been one of the neglected provinces in social reform in modern China It is only since the war that it has come into the limelight There can be now no turning back, for Yunnan is, and promises to remain, the most important province of western China; it is no longer the backdoor to China but is destined to play an increasingly important part in her trade with Britain and other foreign countries

A HOSPITAL SHIP

THE Spanish troops who lately took refuge in France included 12,000 wounded, for whom the local resources of hospitals, material, and personnel were insufficient The French government accordingly converted two steamships into hospital ships and sent them to Port Vendres. Marcel Arnaud, who was appointed chief surgeon to the larger of these two ships, the *Maréchal Lyautey*, described his experiences to the French Academy of Medicine on May 16 (*Bull Acad. Méd. Paris*, 1939, 121, 671). During her month's stay at Port Vendres the *Maréchal Lyautey* dealt with over 1500 Spanish wounded, having 1200 on board at once. She also treated about 300 out-patients from the town There were, Arnaud says, 1080 beds, with palliasses and bedclothes, in four well-ventilated holds furnished with lavatories and water-closets. The second-class and third-class cabins, each with four or five beds, were reserved for the more seriously wounded and for those who had just been operated on There were five operating-theatres: three for septic cases; one for clean cases; and one for plasters One of them was also used as a dressing-station, and there were five other dressing-stations, four of them being in the holds. Two ambulances were used for evacuating the patients, a lorry for carrying supplies, and a car for the chief physician. There were five surgical teams, each consisting of a surgeon and two assistants, and a medical team of three physicians, of whom one acted as radiologist. Besides these the ship carried a dispenser, and another surgeon who specialised in treating fractures of the mandible. The forty French red-cross nurses were later joined by three Spanish nurses Arnaud adversely criticises their floating head-dress, which was very inconvenient when dressing a wounded man lying on the ground, was always getting caught up in wards crowded with beds, and was dangerous in the operating-theatre. He also suggests that it should be compulsory for every one of them to carry, as part of her uniform, a stout pair of scissors for cutting bandages.

Forty of the least severely wounded Spaniards were pressed into service as interpreters, stretcher-bearers, additional nurses, and in different fatigue-duties One of them became assistant to the radiologist, another acted as masseur, and others were donors of blood Apart from numerous radioscopic examinations, over 200 radiograms were made with the help of portable apparatus. Major operations averaged 6 a day; 800 plasters were removed and only 66 put on—a fact which possibly illustrates the difference between French and Spanish ideas of dealing with war wounds. There was only one case of gas-gangrene; it had come from another hospital. There was no tetanus and no death due to anæsthetic. The deaths totalled 11, of which 9 were in cases of severe wounds previously operated on in another hospital, 1 was from cerebral hæmorrhage in a man whose wound had healed and who was ready for evacuation, and the remaining 1 was from uræmic coma in a man four days after he had had a fracture reduced on board.

All the patients except those whose wounds needed immediate attention were deloused as soon as they arrived. This was done on the after-deck. Their clothes were sent to the steam disinfector on board. After this process many of the wounded were left completely naked, for their clothes were so dirty and so ragged that very few of them could be used after disinfection and despite repeated requests it took three weeks to obtain shirts, trousers, and sandals in sufficient quantity to clothe them again. This was a striking contrast to the supply of medical and surgical material. With only two days' notice it was possible to equip four operating-theatres, and the complaint was made that too much material had been sent.

EPIDEMIC DIARRHŒA OF THE NEWBORN

DURING the years 1926–36 there was in New York city a steady decline in the death-rate of the older group of infants but only a very slight decrease in the neonatal period. The rate in infants from one month to one year old dropped from 35 5 to 17 8 per 1000 live births, whereas that in infants from birth to one month decreased only from 32 3 to 27·7. Although the neonatal deaths were no doubt partly due to birth injury, congenital malformations and prematurity, S. Frant and H. Abrahamson (*N Y. St. J. Med* 1939, 39, 784) urge that the important part played by infections, especially diarrhœal diseases, as a cause of illness and death has not been sufficiently emphasised. In 27 outbreaks of infantile diarrhœa in New York city between July, 1934, and December, 1937, the total number of exposed live-born babies was 5082, of whom 750 were attacked and 356 died, the mortality being 47 per cent. There was no instance of the disease spreading to older children or adults. Sex or race did not affect the incidence, nor was there any significant difference between artificially fed and breast-fed infants. The highest percentages of morbidity and mortality were found in the winter months. Bacteriological examination of the nasopharyngeal secretions and of the stools, and agglutination tests of the blood were consistently negative.

During November, 1937, a disastrous epidemic of infectious diarrhœa broke out in the Memorial Hospital at Worcester, Massachusetts. According to A. M. Kimberly (*New Engl. J. Med.* April 20, 1939, p. 664) the infection could be traced to an infant discharged from a hospital in New York city, and the clinical pictures of the babies at Worcester were identical with those in New York. Of the six babies affected five were in hospital for prematurity or feeding difficulties and were grossly underweight, and

all these five died Nearly all the babies acquired some kind of respiratory infection before death, but the post-mortem findings in the gastro-intestinal tract were slight The predominant organism in the stools was *Bacillus welchii*, which was not regarded as significant, and Kimberly suggests that the primary cause was a virus

TOTAL ŒSOPHAGOPLASTY

THE radiological appearances of an œsophagoplasty performed some six or seven years previously are described by P L Fariñas in *Vida Nueva* (April 15, 1939, p 194) The original operation had been done by D Fernández, who reported the case to the Pan-American Medical Association in January, 1938 It was done in three stages in the first a jejunostomy was made in the third left intercostal space close to the sternum, together with an anastomosis between the stomach and the jejunum and another between the upper and the lower parts of the jejunum, two months later the upper part of the œsophagus was used to form an œsophagostomy 3 cm above the clavicle, and in the third stage an artificial œsophagus of skin was constructed to connect the œsophagostomy with the jejunostomy With the aid of radio-opaque liquids and pastes Fariñas studied the action of this artificial œsophagus and observed considerable dilatation of the cervical (true) œsophagus and a circular stenosis where the artificial gullet began The meal was passed by strong contractions of the cervical œsophagus into the artificial, where it caused some distension owing to the partial resistance to its further progress Later, when the whole of the artificial œsophagus was filled it was dilated uniformly except in its terminal portion Here there was a slight kink *where the artificial* œsophagus joined the jejunum, and just proximal to it there was further dilatation or even ectasia The cutaneous portion of the tube, after the meal had passed through it, remained distended with air which had been swallowed The meal passed through the jejunal portion to the stomach in the same way as it does through a normal jejunum and was subjected to segmentation by the action of the valvulæ conniventes Some of the meal entered the stomach and some passed through the remainder of the jejunum Fariñas concludes that the patient's artificial œsophagus works perfectly

DUM-DUMS UNDER X RAYS

IN any war the other side always uses dum-dum bullets, and on the slightest pretext a protest is made, as though their use were a very serious infringement of the rules of "civilised" warfare As we have previously pointed out (*Lancet*, 1936, 1, 1309), an ordinary rifle bullet sheathed with nickel and fired at less than 200 yards' distance, with a muzzle velocity of over 2300 ft per sec, causes a large ragged wound of entry, because of the terrific force of impact and because it wobbles in the earlier part of its flight Ignorance of this fact often leads to the accusation that dum-dum bullets have been used On the other hand, a soft-nosed bullet, in which the sheath is not continued to the tip, is used in elephant-guns for killing big game, it is not meant to pass through the animal's body but to stop the beast with a violent blow. Thus the effect of a dum-dum bullet can be produced by a standard bullet fired at short range with a high velocity rifle, or by a soft leaden bullet fired with a low-velocity firearm Further, a hard sheathed bullet can be "dum-dumised" by partly stripping off its sheath

A Grilli has attempted to distinguish these different types of missiles radiographically, both from his experiments on wooden planks and from human material examined in the military hospital for native troops at *Asmara* during the Abyssinian war and the subsequent "police operations" (*Quad di Radiol* 1938, n s 3, 114) He recognises that it is very difficult to decide from the appearance of a wound whether it was due to a dum dum bullet, because a similar effect can be produced by an ordinary bullet fired at close range or by a ricochet The same remark applies to a wound caused by an explosive bullet (which Grilli accuses the Austrians of being the first to introduce in the Great War) Even radiographically no distinction can be made between true dum-dum—i.e, soft-nosed—and "dum-dumised" bullets, both undergo much deformation and litter the wound track with particles of the metal sheath On the other hand, radiography distinguishes clearly between standard sheathed bullets and those with a partial sheath or none If the bullet has not struck a bone, it can sometimes be identified by its shape, calibre, length, and deformation and it is possible to say whether it is a ricochet Regulation bullets sometimes leave metallic particles of the sheath, which of necessity does not cover the base of the bullet and so can be stripped upwards and broken off Deformation of a bullet in a wound is not always clear evidence, because it may have struck something else before entering, but a naked bullet (without a sheath) becomes deformed in a typical way during its trajectory and can be recognised by flattening of the nose and expansion of the base

TANGANYIKA ARROW POISONS

THE use of poisoned arrows by the Ethiopians was described by Theophrastus in the fourth century B C., and there have been intermittent references to these lethal weapons in the writings of Portuguese and other Europeans visiting Africa ever since Their main use now is in killing game, but they are still of medicolegal interest in parts of East and Central Africa, and according to W D Raymond (*E Afr med J*, March, 1939, p 419) 7 out of 39 post-mortem examinations done lately in the Musoma district have revealed evidence of their homicidal use

The arrows are some 3–5 in long, with an iron tip wrapped with a vegetable material soaked in the poison In 1888 Arnauld isolated from Somali arrows a toxic principle which he named ouabain, prepared from *Acokanthera ouabaio*, and Raymond has found that most of the poisoned arrows in Tanganyika are tipped with preparations of one of the three indigenous acocanthera, though some carry extracts obtained from *Strophanthus emini*, or from local varieties of adenium, scilla, or urginea All of these contain glucosides with a cardiac action similar to that of strophanthin, and it is remarkable evidence of the accuracy of observation of these tribes that they have utilised almost all the known indigenous cardiac glucosides in this way Raymond has found some arrows carrying enough poison to kill 250 men, and he says that in human subjects death usually follows a wound in from twenty minutes to two hours There are no characteristic post-mortem findings in arrow poisoning, but some African chiefs say they can recognise it by the appearance of the skin

INTESTINAL OBSTRUCTION BY IMPACTED FOOD

A CURIOUS case of acute intestinal obstruction is described by H J Postel (*Ned Tydschr Geneesk* 1939, 83, 1959)

The patient, a man of 72, walked into the surgery at 9 o'clock at night, complaining of acute abdominal colic He had taken a meal at noon, consisting only of mashed potatoes Three hours later he had vomited, and colicky pain had begun, at first in the epigastrium and later all over the abdomen The bowels had acted two hours after the onset of the pain, but the patient noticed that no flatus was passed Before the attack he had been in good health Physical examination revealed nothing but slight distension of the central part of the abdomen A mild sedative was prescribed and the patient sent home to bed

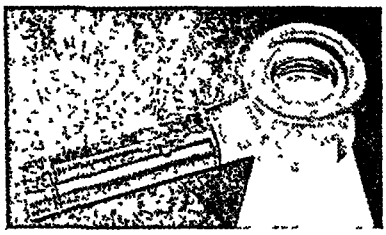
Next morning he was no better, and complained of nausea. The tongue was dry and coated and the abdominal distension had increased He was therefore sent to

hospital for operation. This disclosed a soft mass impacted in the small intestine about 12 in. above the ileocæcal valve, with considerable distension of the bowel above it. The foreign body was removed and turned out to be a piece of dried apple which had swollen after ingestion so as to obstruct the bowel The patient on being questioned recollected that he had eaten a few rings of dried apple, which for lack of teeth he had been unable to chew properly

The patient recovered from the operation, but a fortnight later had a pulmonary embolus and died.

AN ILLUMINATED MAGNIFIER

THE "Partington" illuminated magnifier illustrated here is intended to supply a good light and a moderate degree of magnification for examining or carrying out minor manipulations on the skin or elsewhere. It is some 7½ in. long and consists of a white bakelite head and a metal handle. The head contains a lens system giving a magnification of 10 and a small electric lamp supplied by a dry battery in the handle. When the instrument is placed flat on the skin its surface is accurately in focus, and there is no distortion even at the extreme edge of the field. An aperture at the side of the head allows a forceps or scalpel to be used under full observation.



The magnifier can be obtained from any instrument-maker, price 27*s.* 6*d.*, and it should find many uses in the consulting-room. A more powerful model is now being developed which will give a much higher magnification for eye work and the like.

BACTERIOLOGY WITHOUT TEARS

IN his "Man Against Microbe" (London: English Universities Press. 1939. Pp. 304. 7*s.* 6*d.*) Prof. J. W. Bigger, of Trinity College, Dublin, has tried to present the subject of bacteriology to the intelligent layman in a comprehensive and attractive form, and he has undoubtedly succeeded. In the first section he explains what microbes are, how they are studied and identified by microscopic and cultural methods, their importance in nature and their rôle in the production of disease. In the last two chapters in this section he shows how the animal body attempts to cope with invaders and outlines the methods used in studying the defence mechanism of the body. In the second section Professor Bigger describes the historical development of our knowledge of bacteria and their relation to disease, and in the final section the ways in which disease is contracted and spread amongst men and animals. To the lay reader the first section may seem rather heavy going, and though the descriptions of technical methods that it contains are accurate and clear some of them might well have been omitted The rest of the book makes up for the pedestrian beginning by being full of interest, though there is no tendency to dramatise a subject which needs no such treatment. Incidentally the book indicates clearly the rationale and value of our present measures of specific treatment and prophylaxis against microbic diseases, and should impress on the reader the rapid advances in knowledge that have been made possible by animal experiment.

BRITISH THUNDERSTORM SURVEY.—Dr. F. R. Humphreys has undertaken on behalf of the Thunderstorm Census Organisation to collect information about causes of injury by lightning or electric current to human beings. He would be grateful for help in obtaining particulars of personal injuries sustained He states that "no publicity will be given to individual cases, and the information will only be used for scientific record." Copies of the questionnaire which Dr. Humphreys has drawn up may be had from him at 15, Denton Road, Wokingham, Berks.

Appointments

BRISCOE-SMITH, J. H., M.B. Birm., temporary assistant medical officer for St. Pancras.

CLARK, W. B., M.B. St. And., D.P.H., assistant medical officer of health for Newport, Mon

CRUICKSHANK, ALEXANDER, M.B. Aberd., F.R.C.S., assistant surgeon to the Queen's Hospital for Children, London.

DORRELL, E. W., M.B. Camb., F.R.C.S., assistant resident medical officer at the City of London Maternity Hospital

EVANS, ABEL, M.B. Lond., M.R.C.P., hon. physician to the Cardiff Royal Infirmary.

GABB, W. H., M.B. Camb., M.R.C.P., medical officer at the Chelsea Hospital for Women's convalescent home, St. Leonards-on-Sea

GARMANY, GERALD, M.B. Manc., resident assistant medical officer at Crumpsall Hospital, Manchester

HARDMAN, JAMES, M.B. Birm., F.R.C.S., neurological surgeon to the Royal Sheffield Infirmary and Hospital.

LILLIE, D. C., M.B. Glasg., resident assistant medical officer at Crumpsall Hospital, Manchester

OAKLEY, W. G., M.D. Camb., M.R.C.P., assistant physician to the diabetic department, King's College Hospital, London.

SUMMERHILL, J. H. E., M.R.C.S., resident medical officer at the City of London Maternity Hospital

WITHERS, R. J. W., M.D., M.Ch. Belf., F.R.C.S.E., orthopædic registrar to the Royal Victoria Hospital, Belfast

Births, Marriages and Deaths

BIRTHS

BLEWITT.—On June 30, at the Maternity Hospital, Liverpool, the wife of Captain Basil Blewitt, R.A.M.C.—a daughter

BULLEID.—On July 2, the wife of Dr. A. H. Bulleid, of Midsomer Norton—a son.

CRAIG.—On June 25, at Framlingham, the wife of Dr. D. M. Craig—a daughter

FREW.—On June 29, at Stafford, the wife of Dr. John Frew—a daughter

GREIG.—On June 19, at the Westminster Hospital, the wife of Dr. M. T. Greig—a son

HOUGHTON.—On June 28, at Solihull, the wife of Dr. A. C. Houghton—a daughter

NEWMAN.—On June 30, the wife of Dr. James Newman, of Chichester—a son

NUSSEY.—On June 30, at Bournville, Birmingham the wife of Dr. A. M. Nussey—a daughter

SMITH.—On June 5, in Poona, the wife of Captain Michael Smith, I.M.S.—a son

MARRIAGES

BROWN—BASH.—On July 1, at St. Mary's, Ealing, Arthur Ivor Parry Brown, M.B., to Joyce Marion Bash.

NESFIELD—HIGGINS.—On June 24, at St. Mark's Church, Purley, John Clive Baird Nesfield, L.M.S.S.A., to Stella Mary Higgins

DEATHS

FELDMAN.—On July 2, in London, William Moses Feldman, M.D. Lond., F.R.C.P., F.R.S.E., aged 58

RAFFAN.—On June 28, at Huddersfield, James Raffan, M.D. Aberd., F.R.C.S.E., D.M.R.E., in his 56th year

RANKING.—On July 4, Robert Maurice Ranking, M.D. Camb., M.R.C.P., of Tunbridge Wells, aged 63

WATSON.—On June 27, at Harrogate, William Muir Crawford Watson, M.D. Edin., aged 72

*N.B.—A fee of 7*s.* 6*d.* is charged for the announcement of Births, Marriages, and Deaths*

NUTRITION AND THE PUBLIC HEALTH.—The proceedings of the National Conference on the Wider Aspects of Nutrition held by the British Medical Association last April have now been published under this title Copies of the book (2*s.* 6*d* post free) can be obtained from the association, B.M.A. House, Tavistock Square, London, W.C.1

ADDRESSES AND ORIGINAL ARTICLES

SURGICAL TREATMENT OF ARTERIAL HYPERTENSION*

BY P B ASCROFT, M S Lond, F R C S

ASSISTANT SURGEON AT THE MIDDLESEX HOSPITAL, LONDON; STRATTFIELD RESEARCH SCHOLAR, ROYAL COLLEGE OF SURGEONS OF ENGLAND

HIGH blood-pressure is the commonest cause of death in the second half of life After fifty 1 death in 4 is due to arterial hypertension or its consequences [1] [2] In a series of 82 cases of arterial hypertension studied post mortem by Fishberg [3] 72 were "essential" and only 10 nephritic By essential hypertension he means all cases of chronic hypertension without clinical or anatomical evidence of antecedent renal disease The average age at death due to essential hypertension is fifty five In a group of 420 hypertensive patients death was due in some 60 per cent to cardiac failure, 20 per cent to cerebral accidents, and less than 10 per cent to renal failure [4] The large majority of patients with arterial hypertension die relatively early owing to mechanical strain on the heart and arteries It has been widely maintained that arterial hypertension is a compensatory mechanism designed to improve the circulation to the tissues generally or to a particular organ that requires extra oxygen and nutriment, and on this account a laissez-faire attitude has been adopted towards the treatment of high blood pressure This attitude is encouraged by the observation that chronic hypertensives often feel worse when their blood pressure falls, but the commonest cause of a falling blood pressure in arterial hypertension is failure of the left ventricle, which can by no means be regarded as beneficial.

It is well known that cardiac output is seldom increased in hypertension,[29] pressure being maintained by generalised increase in the peripheral resistance due to narrowing of the arterioles Since capillary pressure approximates to normal,[17] at all events in most of the body, and since metabolic exchanges take place in the capillary bed and not in the arterioles, it follows that the needs of the tissues for oxygen are no better served in the hypertensive than in a person with a normally adjusted circulation Though we are certain that the general efficiency of the circulation is not improved by high arterial pressure, the question of selective circulatory increase cannot be so readily answered It is easy to accept the idea that changes in an organ or tissue whose function is impaired directly by disease or indirectly by reduction of its normal quota of blood may induce an increase in the arterial pressure, with the result that extra blood is shunted towards it The organ that has attracted greatest attention from this point of view is the kidney, which is unique in requiring something more than an adequate rate of blood flow for its proper function A considerable head of pressure in the afferent glomerular arterioles is vital, the average being about 100 mm Hg, and, when the pressure falls below 40 mm Hg, filtration through Bowman's capsule ceases Many accept the theory that hypertension in renal disease is simply an attempt on the part of the body to improve the renal circulation However attractive this teleological reasoning in nephritic hypertension, it cannot readily be applied to essential hypertension, which is ten times commoner Further, those who believe that hypertension is a beneficial compensatory mechanism must admit that the cure is worse than the disease, for 80 per cent of hypertensives die as a direct result of cardiovascular strain, whereas less than 10 per cent succumb to renal failure

The position as regards hypertension may be summarised thus —

(1) There is no increase in general circulatory efficiency There may or may not be increased circulatory efficiency in some particular organ, In other words, hypertension is probably not a beneficial adjustment

(2) Death usually takes place as a direct result of raised blood-pressure

It therefore appears that there is no fundamental objection to methods designed to reduce the blood-pressure in essential hypertension and perhaps in other kinds of arterial hypertension

Factors Controlling Blood-pressure

Before describing the forms of surgical treatment that have been advocated, it is necessary to consider shortly how the blood pressure is regulated in normal circumstances, and how the regulatory mechanism is perverted in essential hypertension Arterial pressure is directly proportional to the product of the cardiac output and the peripheral resistance In essential hypertension and the hypertension of chronic nephritis cardiac output is not raised [29], consequently the rise in pressure is due to increased peripheral resistance, which in turn depends on the calibre of the vessels and on the viscosity of the blood In essential hypertension and the hypertension of chronic nephritis viscosity and the volume of the circulating blood are substantially unaltered [30], hence the only effective factor in increasing peripheral resistance must be narrowing of the blood vessels The lumen of a blood vessel may be reduced by a change in the structure of its wall or by active contraction of its muscular coat Gull and Sutton [31] believed that endarteritis and thickening of the intima, or sclerosis of the media, in the arterioles and capillaries were the cause of hypertension in chronic Bright's disease, but true generalised arterio sclerosis does not exist in association with nephritis, still less with essential hypertension, in fact, as Fishberg [3] says, all available evidence points decisively in the opposite direction—i e, that the hypertension causes such arteriolar lesions as are found † Hypertension, both essential and nephritic, must therefore be due to active contraction of the muscular coats of the arterioles The factors which may directly influence vasomotor tone are either nervous or chemical

NERVOUS FACTORS

Stimulation of vasomotor nerves is known to increase blood pressure, and the notion that vaso-constriction of nervous origin is responsible for arterial hypertension is attractive alike for its simplicity and because it suggests a means of surgical attack But such arguments must not be accepted uncritically More than one surgeon has been duped by scientific confidence tricks of this kind and has become an indiscriminating destroyer of portions of the sympathetic system, to the lasting injury of

* Hunterian lecture delivered at the Royal College of Surgeons on June 2 1938

† The histological evidence of Moritz and Oldt [32] however suggests that renal arteriosclerosis is the primary lesion in essential hypertension

this branch of therapeutics. In 1936 two papers of great importance appeared: Pickering [48] and Prinzmetal and Wilson [55] independently and by different techniques have shown that the pressor agent in essential hypertension and hypertension of chronic nephritis is not nervous The methods consisted essentially of measuring the blood flow in the arms of hypertensives after cutting off all vasomotor impulses thereto. If hypertension is due to nervous constrictor impulses, their removal from a small area of the vascular bed, such as the arm vessels, will cause an abnormal increase in blood flow. This does not, in fact, take place; hence it follows that the abnormal vascular tone is not nervous, at all events in the arm and peripheral circulation generally, although, as Pickering is careful to note, this does not necessarily apply to all internal organs. It is possible to produce hypertension in animals by injecting kaolin into the cisterna magna or by denervating the carotid sinus and dividing the depressor nerves, and it has been suggested that human essential hypertension is due to ischæmia of the medulla oblongata or to disorder of the carotid sinus and aortic reflexes, leading to excessive vasoconstrictor impulses. The observations recorded above dispose of both hypotheses (see also Bouckaert et al.[7] and Pickering et al.[51]).

CHEMICAL FACTORS

Adrenaline.—The powerful pressor action of adrenaline, so often called into play under physiological conditions, renders this substance suspect as a predominating cause of essential hypertension. The opposing evidence is so weighty, however, that it will suffice to summarise it to shatter what Janeway [37] has called "the beautiful dream of adrenalinæmia."

(1) Using a test capable of detecting adrenaline in a dilution of 1 in 700 million, Hülse [35] examined the blood of hypertensives and found no trace. This has been confirmed by Rogoff and Marcus.[56]

(2) Minute doses of adrenaline dilate rather than constrict blood-vessels.

(3) Pressor doses of adrenaline reduce the peripheral blood flow. This is unaltered in essential hypertension.

(4) Pickering and Kissin [50] find that patients with essential hypertension or chronic nephritis are not unduly sensitive to adrenaline.

(5) The rare instances of paroxysmal hypertension known to be due to tumours of the suprarenal medulla do not resemble essential hypertension and are promptly cured by removal of the tumour.

(6) Denervation of the suprarenals, with or without destruction of the medullary tissue, does not substantially reduce the pressure in essential hypertension.[21 27]

Suprarenal cortex.—Tumours of the suprarenal cortex occasionally appear to be the cause of paroxysmal hypertension, and hyperplasia of the cortex has been observed in essential hypertension, especially when associated with Cushing's syndrome. Such hyperplasia is, however, more often absent in hypertension and often present when the blood-pressure is normal, and there appears to be no reason to regard the average case of essential hypertension as due to disorder of the suprarenal cortex.

Pituitary.—In 1932 Cushing [15] drew attention to a peculiar condition, now known by his name, in which a basophil adenoma of the pituitary gland is associated with hypertension and certain striking bodily changes Cushing put forward the theory that an excessive secretion of the pressor principle of the posterior lobe of the pituitary was responsible for the hypertension. This theory has been extended to serve as a possible explanation of the raised pressure in essential hypertension; but, before it can be accepted as an explanation of the average case, it remains for this pressor principle to be demonstrated in the blood or in the cerebrospinal fluid of essential hypertensives Further, the clinical features of Cushing's syndrome are so dramatic that one cannot accept too close a comparison with ordinary cases of high blood-pressure. It must, however, be admitted that this is no argument against the raised blood-pressure being due to the same cause in both types of case. Page and Sweet [46] have shown that hypophysectomy in dogs with experimental renal hypertension often reduces the blood-pressure to the normal level, but they believe the effect to be indirect and not due to removal of the pressor principle of the posterior lobe of the pituitary. It is possible that the pituitary gland may play a part in the form of hypertension known as climacteric, which affects women passing through the natural or artificial menopause.

Other vasoconstrictor substances.—Since the vasoconstriction which is responsible for arterial hypertension *is not nervous and there is no good reason* to incriminate the endocrine glands, we must look elsewhere In the last few years a very considerable body of evidence has accumulated pointing to the kidney as the origin of the pressor substance Before passing on to discuss the rôle of the kidney, we may mention briefly some of the older views on the ætiology of high blood-pressure, as taught to students a few years ago. These are epitomised in the familiar mnemonic G L A S S: G for gout, L for lead, A for alcohol, S for syphilis, and S for strain. Gout and lead poisoning are unimportant nowadays Alcoholism and indulgence of all kinds have been blamed for hypertension among other evils, but alcoholics have a low rather than a high blood pressure, and cardiac hypertrophy is uncommon among them Gluttony has long been held to be a potent cause of high blood-pressure, and no doubt they are often associated. Just how overeating causes high blood-pressure is by no means clear. Consumption of large quantities of meat and other proteins has been held responsible, without good evidence, and those hypertensives of carnivorous tendencies whose doctors forbid them meat might quote the interesting case of Stefannson, the arctic explorer, who spent eleven and a half years within the arctic circle, nine years of which he subsisted on meat alone, including a period of nine consecutive months. His blood-pressure was 115/55. Tobacco may be a subsidiary factor of some importance Dixon (1918) found that smoking of a Manila cigar by a novice caused a rise of 20 to 25 mm. in systolic pressure (which was followed half an hour later by a sharp fall), and others [33 34 38 40] have shown that a single cigarette causes distinct peripheral vaso constriction and often a rise in blood-pressure. Syphilis has been accorded a prominent place among the causes of high blood-pressure. Fishberg,[20] however, does not find the incidence of positive Wassermann reaction greater in hypertensives than in the general hospital population.

Hard work and hard living are widely believed to be important, if not predominant, causes of essential hypertension, but the athlete and the manual worker are no more prone than the clerk to high blood pressure The danger does not appear to be physical strain but what is popularly known as "the strain of modern life." There is some doubt, however, whether this portentous phrase means much more than the manifold worries and irritations which beset us all. Those who live high-pressure lives are perhaps more liable to hypertension; on the other hand, there

are many with hypertension who appear to be without a care and to have led a completely sheltered existence Neurasthenics usually have low blood-pressure Fishberg[20] sums up as follows:—

"In all probability, emotional and mental strain play purely an accessory rôle in the genesis of essential hypertension, serving to precipitate or aggravate the increase of blood pressure in those individuals who have inherited some constitutional predisposition to essential hypertension, which is of such fundamental importance"

RÔLE OF THE KIDNEY

Since the days of Bright (1836),[3] who first observed the association of chronic nephritis with enlargement of the heart and thickening of the blood vessels, until the end of the century hypertension was believed to be due to renal disease or to arteriosclerosis With the introduction of the baumanometer by von Basch (1893)[4] and the brilliant work of Clifford Allbutt (1895 and later)[1] it became evident that hypertension was extremely common and previous clinically recognisable renal disease the exception In recent years attention has again been focused on the kidneys, particularly by the experiments of Goldblatt and his associates,[21-25] who have crystallised the tentative work of numerous investigators by developing a standard technique for producing persistent hypertension of renal type in animals They partly occlude one or both renal arteries with adjustable clamps and find that loose constriction causes no rise in pressure, whereas moderate constriction causes the pressure to rise within a few days or weeks to a level often double the normal and to remain at a high level for at least five years If the arteries are severely constricted, pressure rises rapidly, often to a very high level, and the animal dies in uræmia within weeks or months If the arteries are totally occluded, the animal dies of renal failure within a few days, often with a fall in pressure. Similar constriction of other vessels, such as the splenic, mesenteric,[19] or both femoral arteries, does not affect the blood pressure Since some of Goldblatt's dogs have been observed to have a systolic pressure of 250 mm for five years without signs of renal failure, the resemblance to essential hypertension in man is striking, and in the hope of elucidating the mystery of essential hypertension Goldblatt and others have made the following observations in experimental hypertension due to renal ischæmia —

(1) This form of experimental hypertension is not due to renal failure, because (*a*) in most instances clinical and chemical signs of renal failure do not develop at all or only after years, and (*b*) constriction of the main artery of one kidney without interference with the other often causes a considerable rise of pressure persisting for months If the ischæmic kidney is excised, the blood pressure quickly falls to normal[26] There is a striking parallel to the observation in human pathology Several cases have recently been reported of unilateral "surgical" kidney (the other kidney being sound) associated with arterial hypertension[2,3,30], removal of the affected kidney was followed by fall of pressure to normal

(2) Hypertension due to moderate constriction of the renal artery is not due to fixed changes in the renal parenchyma If the clamps are removed after hypertension has developed, the pressure promptly falls to normal.[26]

(3) Hypertension is not due to nervous impulses The kidneys may be denervated,[27] the splanchnic nerves may be cut,[27] or the animal may be totally sympathectomised,[21] without more than momentarily reducing established hypertension and without preventing it when the renal arteries are subsequently constricted Again, hypertension develops in the usual way when a transplanted kidney is rendered ischæmic[6] Denervation or destruction of the adrenal medulla is equally ineffective in preventing or reducing hypertension[28]

(4) Goldblatt[22] has shown that excision of both suprarenal glands prevents or reduces the hypertension of experimental renal ischæmia, even when the animal is kept alive for months with sodium salt treatment If only a fragment of cortex remains, or if cortin is given, the pressure is not reduced Houssay[19] interprets this as meaning that cortin favours the production of vasoconstrictor substance by the kidney or renders the *vasoconstrictor mechanism* sensitive to its action

(5) A pressor substance may be prepared from ischæmic kidneys

Forty years ago Tigerstedt and Bergmann[37] prepared a pressor substance from normal kidneys This pressor substance has been called renin, and recently Pickering and Prinzmetal[38] and Landis et al[39] have extracted it from normal kidneys in considerable quantity and demonstrated its extraordinarily powerful and prolonged pressor action Landis makes the important point that renin, unlike adrenaline, pituitrin, and other substances that raise the blood-pressure, does not decrease the peripheral blood flow—a most significant observation, for neither is peripheral blood flow decreased in human hypertension. Harrison et al[33] and Prinzmetal and Friedman[34] claim to have demonstrated abnormal quantities of renin *in ischæmic kidneys of hypertensive dogs* Houssay and his co workers,[19] in a superb series of experiments, confirm the growing impression that hypertension of renal ischæmia is due to a pressor substance formed in the affected kidney They grafted the ischæmic kidneys of hypertensive dogs on to the main neck vessels of normal dogs and found a consistent and prolonged rise in blood-pressure One animal of their series possessed a kidney with two renal arteries One was constricted by an adjustable clamp rendering half the kidney ischæmic When this kidney was transplanted, the unconstricted renal artery was first anastomosed There was no rise in pressure The constricted artery was then anastomosed, and the pressure rose

Houssay suggests that this renal pressor substance (renin) is eliminated or destroyed by the normal kidney, and he summarises his evidence as follows. (*a*) *when the renal artery to one kidney is constricted*, a moderate slow rise of pressure takes place, which often falls to normal, (*b*) if the healthy kidney is then removed, there is a rapid rise in pressure, (*c*) the grafted ischæmic kidney has a greater pressor effect in nephrectomised dogs than in those with normal kidneys; and (*d*) in an animal with one renal artery constricted venous blood of the sound kidney had less vasoconstrictor effect than its arterial blood As the last statement implies, Houssay has demonstrated a pressor substance in the venous blood of ischæmic kidneys which has a powerful vasoconstrictor action, so removing a serious objection—namely, failure to demonstrate a pressor substance in the blood—to the renin theory of experimental renal ischæmic hypertension

To sum up, severe hypertension may be established in animals by partial constriction of the renal arteries. It is due to excessive production or abnormal action of a pressor substance (renin) in the affected kidney. This substance is present in the normal kidney and is eliminated or destroyed by the normal kidney

The action and/or production of renin is influenced by the suprarenal cortex

Surgical Treatment

Nearly all the operations to be described, designed to reduce arterial hypertension in man, are directed towards denervation of the kidneys, suprarenal glands, and the splanchnic area, since surgeons have believed (partly on faulty and incomplete evidence, partly wishful thinking) that essential hypertension is largely due to excessive vasomotor activity of nervous origin. From the evidence so far adduced the prospect of success of operation on the sympathetic nerves for hypertension seems remote; but the proof of the pudding is in the eating, and the results of surgical treatment of human hypertension will now be examined, the relation of human and experimental hypertension discussed, and possible accessory surgical methods mentioned.

In 1923 Pende recommended section of the left splanchnic nerve; in 1925 Brown and Pointer performed bilateral lumbar sympathectomy without success; in 1928 Crile treated 5 patients by removal of one suprarenal gland, without any fall in pressure, and in 1937 Friedman and Eisenberg [23] reported 5 patients treated by bilateral partial adrenalectomy, of whom 2 died of adrenal insufficiency and 3 were unimproved. Denervation of the kidneys by stripping the renal pedicle is equally disappointing (at all events in advanced cases, but see Pickering [43]). In none of these patients was there serious renal impairment.

The only "denervating" operations which have been at all encouraging involve division of the sympathetic nerves of the splanchnic area. This may be carried out in four ways:—

(1) By interrupting the sympathetic outflow by cutting the anterior nerve-roots from the sixth thoracic to the second lumbar segment.
(2) By dividing the splanchnic nerves and the sympathetic chain above the diaphragm.
(3) By dividing the splanchnic nerves and lumbar chain below the diaphragm.
(4) By removal of the cœliac ganglia.

(1) Page and Heuer [45] report 17 patients, all having diastolic pressures of over 120, treated by section of some half a dozen pairs of anterior nerve-roots from the mid-dorsal region downwards. Their patients were observed eight months to three years after operation, and 4 of the 17 did well. Headache, nervousness, dizziness, fatigue, palpitation, and even fits were relieved, and the blood-pressure fell to 160/100 or lower. A girl of twenty-three,[44] whose blood-pressure before operation was 190/122, was free from symptoms two and a half years later, and her blood-pressure was 150/96 (Fishberg puts the upper limit of normal blood-pressure at 150/90). An inevitable effect of this operation of anterior root section is paralysis of the abdominal wall This is said to be good, for it allows blood to drain into the splanchnic vessels more readily; but a paralysed abdominal wall is a mixed blessing even in a hypertensive. For this reason and because the necessarily extensive laminectomy is severe and has been followed by transverse myelitis other means of splanchnic sympathectomy are generally used.

(2) Max Peet divides the splanchnic nerves above the diaphragm and resects the lower three ganglia of the thoracic sympathetic chain. The nerves are approached by resecting a small piece of the eleventh rib, and both sides may be dealt with at one stage His operative mortality in 156 patients is 3 8 per cent.

Frehberg and Peet [22] recently reported results of his operation in 48 patients, whose average age was forty-six, observed three months or longer after operation: 6 were free from symptoms and their blood-pressure was reduced to 160/100 or lower; 8 showed a fall of more than 60 mm. systolic or 30 mm. diastolic; 10 a fall of 30 to 60 mm. systolic or 15 to 30 mm. diastolic; and in 24 the pressure did not fall. An example of a successful case is a man, aged twenty-nine, whose pressure was 236/160. Over two and a half years after operation it was 156/100. Another patient, aged twenty-two, had had hypertension for at least three years. The pressure was 280/190. One year after operation it was 132/95.

Peet [36] now reports the results of his operation in 315 patients in the last five years, claiming "complete recovery in 15% and distinct and permanent lowering of the blood pressure in about half." Peet's cases have been closely studied with regard to renal function, and the important suggestion emerges that, should a patient with some renal impairment react favourably to operation, renal function will improve proportionally to the fall in blood-pressure, and signs of impairment may disappear entirely. Davis and Barker [16] have performed Peet's operation in 6 carefully controlled cases, and they found that in each the blood-pressure had risen to the preoperative level with return of all the distressing symptoms. They found, however, that these patients had become susceptible to cyanate treatment, to which they had not responded before operation.

(3) Adson [2] and his associates at the Mayo Clinic carry out an extensive sympathectomy in two stages by a modified renal approach. The three splanchnic nerves, most of the cœliac ganglion, and the upper two lumbar ganglia and chain are removed on each side, so denervating the suprarenals, splanchnic vessels, and the kidneys. In his earlier cases Adson removed a portion of each adrenal, but he has not done so for the last two years, and the effect of the operation is not reduced. Of 44 cases observed for two to twenty-three months the results are given as good in 11, fair in 13, and poor in 20. By good is meant complete or nearly complete symptomatic relief and a blood-pressure of not more than 160/100. For example, a patient whose maximal pressure was 225/130 and minimal pressure 150/100 was well fifteen months later with a pressure of 128/90. Altogether 156 patients have now been operated on at the Mayo Clinic by Adson's method, and "functional cure" is claimed in 83 per cent.[36]

(4) Crile,[13 14] of Cleveland, has practised bilateral removal of the cœliac ganglion in some 140 patients. He claims symptomatic relief in 78 per cent. of patients, and the operative fatalities are limited to 3 in the last 123 patients. Of 19 patients seen seven months after operation, 3 are reported as having a normal pressure; but Crile does not say what he means by normal—in fact, his tables of results are so difficult to interpret that one cannot usefully quote further figures.

ASSESSMENT OF RESULTS

We now turn to the problem of assessing the value of surgery. To do so accurately is not yet possible. There is no question that improvement of symptoms and blood-pressure often takes place after splanchnic section, but similar improvement is the rule in most patients with hypertension when simply put to bed Nevertheless, we cannot escape the fact that in some instances surgery has relieved the victims of severe essential hypertension of all symptoms and has rendered them capable of full work, blood-pressure remaining at a normal level for years. An

instance of this kind was recently described by Ogilvie,[42] who writes

"Four years ago a surgeon of about 40 was forced by rising blood pressure, inability to concentrate, headaches becoming at times intolerable and failing vision to resign his university post and abandon his practice He underwent the operation of bilateral splanchnicectomy and immediately lost all his symptoms and returned to a normal blood pressure He obtained another post at a university in another State, and has been in full work ever since, his blood pressure showing no tendency to rise again I had not the good fortune to meet him, but I met many of his colleagues, and they are agreed that he is now able to work as hard as any of them To my question as to whether he was as good a man as before his symptoms appeared, they replied that he had lost some of his fire, he was not the 'go-getter' he used to be, but he was *still a fine surgeon*"

Though most physicians through whose hands pass many cases of essential hypertension can recall instances of extraordinary symptomatic recovery and some years of useful life in patients apparently at death's door, it appears to be extremely rare for the blood pressure to return to normal or near normal for any length of time There is strong evidence, therefore, that splanchnic section is sometimes dramatically successful The puzzle is to select suitable cases First, it should be recognised that most hypertensives improve with rest and the usual medical measures, that the average life of a hypertensive moderately afflicted is ten years after the hypertension is first discovered, and that many persons with a systolic blood pressure of 200 and more lead an active and fruitful life Whatever part it may eventually play, surgery has today no place in the treatment of the early stages of hypertension Operation should be confined to victims of severe hypertension—e.g, with a pressure frequently rising to 200/120 and more—whose symptoms are troublesome, and who do not readily improve with rest This group must be further pruned by eliminating those with distinct renal or myocardial failure or widespread arterial sclerosis, and operation is best avoided after the age of fifty Of the considerable number of potential candidates for surgery that remains it is found by experience that less than a quarter will obtain notable benefit from operation Unfortunately there is no infallible means of recognising those cases that will respond favourably except trial by ordeal—i.e, by the operation itself This is the method employed *in cancer surgery* Those patients with gross dissemination are eliminated, but we are obliged to operate on the rest knowing that two thirds of them are already doomed by dissemination, then undetectable, but not knowing who will be saved and who taken But, whereas the surgery of cancer is established, that of hypertension is experimental, and it is wrong to sacrifice the majority in favour of the odd case that might benefit Adson,[10] Child,[11] and Craig [12] have shown that those patients are most likely to respond whose blood-pressures approach the normal when at rest or asleep, when given nitrites, and particularly when lightly anæsthetised with drugs such as sodium pentothal If to these tests there is no appreciable fall in pressure, the hypertension is said to be fixed, and splanchnic section will almost certainly fail Unfortunately a good response to *these tests, though* hopeful, is no guarantee of a good response to operation Another test, which is attractively direct, is to induce temporarily the effect of splanchnic section by paralysing the splanchnic nerves by injection of Novocain I have tried this method and believe that it is unsatisfactory, for, if there is no fall in blood pressure, it may be because injection is misplaced, and, if the pressure does descend, it is as likely to be due to syncope as to splanchnic paralysis, for the procedure causes distress

CORRELATION OF EXPERIMENTAL WORK AND SURGICAL RESULTS

It remains for us to try to explain the results of splanchnic section why it often has no effect on the blood pressure, and why it is sometimes followed by a fall to normal It may be postulated that in the early stages of essential hypertension blood flow to the renal tissue is reduced by constriction of the renal blood vessels, especially afferent glomerular arterioles, by nervous impulses. This causes excessive production of renin, which enters the blood stream, causes generalised vasoconstriction, and raises the blood pressure If splanchnic section is undertaken at this stage, the renal arteries dilate and blood pressure falls If not, structural changes take place in the arteries, not only rendering dilatation impossible but also causing further narrowing More renin is produced, a vicious circle is established, and hypertension becomes permanent and progressive The importance of high intra-arterial pressure as a *mechanical factor in producing lesions of the renal* arterioles is proved by Wilson and Byrom's [55] recent demonstration in rats of renal vascular lesions typical of malignant hypertension When the rat is rendered hypertensive by constriction of one renal artery, gross arterial changes are found in the opposite kidney but not in the ischæmic one, whose clamp protects it from the general hypertension

OTHER MEANS OF SURGICAL TREATMENT

There is a close resemblance between essential hypertension and experimental hypertension due to renal ischæmia, and it seems probable that a pressor substance like renin is at work in man as in animals The outstanding objection to the chemical (renin) theory of essential hypertension is failure to demonstrate a pressor substance in the blood Transfusion of even 2 litres of blood of a hypertensive into a normal person does not cause a significant rise in pressure,[47 48] but in these experiments the recipient's kidneys were normal, and there is some evidence to show that normal kidneys remove the pressor substance [49] The high level of pressure in essential (and nephritic) hypertension is maintained chemically, and the pressor substance is probably of renal origin and may be identical with renin *Assuming for a* moment the truth of the renin theory, what is to be done? The obvious course is to improve the renal blood supply Goldblatt [26a] states

"If before constricting the renal artery, the kidney is decapsulated and adipose tissue or muscle is attached to the denuded cortical surface, the accessory circulation becomes very prominent and interferes with the development of permanent elevation of blood pressure"

The astonishing power of vascularisation possessed by the omentum is familiar to surgeons and has been applied in the operation of cardiomyopexy, developed by O'Shaughnessy [43a] According to Samaan grafting of the omentum on to the decapsulated ischæmic kidney in a hypertensive animal so improves the renal blood supply that the blood pressure falls to normal. This, if true, is an observation of the first importance, but it awaits confirmation Even if successful in animals it would not necessarily work in man The essential difference between hypertension due to experimental renal ischæmia and human hypertension is the site of arterial narrowing

Experimentally, the main renal artery is constricted; in man the afferent glomerular arterioles are probably involved. To benefit human hypertension it would therefore be necessary to establish arterial communications of sufficient size with the afferent glomerular arterioles to raise the pressure therein. Nephro-omentopexy could readily be combined with subphrenic splanchnic denervation, the capsule being stripped from the left kidney and the omentum brought through an incision in the peritoneum and wrapped round it. The *right* kidney might also be decapsulated in the hope of acquiring a subsidiary blood-supply from the perirenal tissue. It is probably unwise for technical reasons to attempt right or bilateral nephro-omentopexy.

Summary and Conclusions

(1) After the age of fifty 1 death in 4 is due to arterial hypertension.

(2) Renal failure is the cause of death in less than 10 per cent of cases of arterial hypertension.

(3) Whatever the initial cause of raised blood-pressure in "essential" arterial hypertension, the hypertension itself is the dangerous factor and the commonest cause of death.

(4) The general circulatory efficiency is not increased in essential hypertension.

(5) Consequently, there is no fundamental objection to reducing the blood-pressure in essential hypertension.

(6) Essential and nephritic hypertension is maintained by generalised arterial and arteriolar constriction which is not nervous but chemical.

(7) The hypertensive factor in experimental hypertension due to renal ischæmia is a pressor substance of renal origin known as renin. Human essential and nephritic hypertension closely resemble this form of experimental hypertension.

(8) Surgical treatment of arterial hypertension is still in the experimental stage. Of the operations so far performed wide splanchnic denervation is the operation of choice. Operation should be limited to a small and carefully selected group of patients with severe but still labile hypertension. The result of operation is predictable up to a point but never certain. Brilliant successes have been reported.

(9) Nephro-omentopexy in addition to splanchnic sympathectomy may be of value.

I have great pleasure in recording thanks to Prof. John Beattie for continued help and advice and for the facilities afforded me in his laboratories.

THE MECHANISM OF DIABETES MELLITUS*

By H. P. Himsworth, M D Lond, F.R C.P
DEPUTY DIRECTOR, MEDICAL UNIT, UNIVERSITY COLLEGE HOSPITAL, LONDON

II—THE CONTROL OF THE BLOOD-SUGAR LEVEL

(Continued from p 68)

RÔLE OF THE LIVER

The discovery by Claude Bernard that the liver secretes glucose into the blood led him to state that the liver was of prime importance in the *maintenance of the normal blood-sugar level*. His suggestion has been fully confirmed by the experiments on hepatectomised animals.[91] An excellent picture of the functioning of the liver in ordinary circumstances is provided by experiments demonstrating the effect of ingestion of glucose on the inflow and outflow of sugar from the liver. Recently Tsai and Yi[133] have demonstrated that, whereas the liver in the fasting state secretes glucose into the blood, when an excess of glucose enters the blood glucose is removed by the liver. This work has been confirmed in greater detail by Soskin and his colleagues,[125] who have shown that after the hyperglycæmia caused by injection of glucose the liver

* The Goulstonian lectures for 1939 delivered before the Royal College of Physicians of London on March 2, 7, and 9. Lect I and the first part of Lect. II appeared in our issues of July 1 and 8, and Lect III, together with the references, will appear in a later issue.

ceases to secrete and stores sugar until the blood sugar level falls to normal Then there is a period during which sugar flows neither in nor out of the liver, and finally the liver begins to secrete glucose again These results are readily interpreted on the basis of the adjustment of the head of pressure of blood sugar to the needs of the tissues In the *fasting* state the liver supplies sugar to the blood in proportion to the peripheral utilisation, and the head of pressure of sugar in the blood thus remains constant Exogenous hyperglycæmia supplies the tissues with abundant sugar, and the utilisation of this sugar by them is aided by the secretion of pancreatic insulin As a result the tissues are satiated with sugar and the liver, being no longer stimulated to secrete, is able to store sugar With the subsidence of hyperglycæmia the peripheral tissues now contain carbohydrate in excess of their needs and the liver is not stimulated to secrete glucose until this excess of carbohydrate is disposed of and the normal needs of the tissues again establish themselves The reaction of the liver to a fall in the head of pressure of blood sugar below that requisite for the needs of the tissues is well exemplified in the sequence of events following the administration of phloridzin In the attempt to prevent the head of pressure of sugar in the blood from falling under the steady drain of glycosuria the stored liver glycogen is broken down and liberated as glucose into the blood When this source is exhausted, the liver breaks down body proteins to sugar, and combustion of fat proceeds at an increased rate The accelerating combustion of proteins and of fat is reflected in the urine by increasing excretion of nitrogenous substances and of ketone bodies After removal of the pancreas a similar increased combustion of protein and fat takes place, and the dependence of these processes, as well as the maintenance of the blood sugar at high levels, on hepatic activity is shown by their disappearance after hepatectomy [91 95 102] The manner in which the various endocrine glands influence these reactions of the liver has already been discussed

Little is known about the mechanism which controls the liver in its accurate and rapid adjustment of the blood sugar level Although the action of adrenaline in *stimulating* hepatic glycogenolysis is adequate to explain the recovery of the blood sugar level when this falls below 70–80 mg per 100 c.cm,[19] it is not adequate to explain either adjustment at higher blood sugar levels or the prompt and delicate adjustment at normal levels The existence of some other mechanism is suggested by the extreme susceptibility of *animals* injected with anterior pituitary extracts to emotional hyperglycæmia and by their normal response to intravenous adrenaline That the mechanism of adjustment is extremely sensitive is shown by experiments with pancreatic grafts in otherwise depancreatised dogs, within a few minutes of excluding the graft from the circulation the blood sugar begins to rise, only to return and remain at normal levels again when the circulation to the graft is restored [47] According to Macleod [88] *stimulation* of the hepatic nerves can initiate glycogenolysis in the liver, and it may be that not only the immediate adjustment of hepatic outflow of sugar but also the secretion of the anterior pituitary gland are controlled by some centre in the brain which is extremely sensitive to decreasing utilisation of carbohydrate whether this be due to lack of carbohydrate or impaired ability to deal with the carbohydrate available

The question of the interaction of the liver and the blood sugar level cannot be left without considering the interesting hypothesis of the homeostatic function of the liver advanced by Soskin [121 125] and widely accepted in America According to this theory the decision as to whether the liver secretes sugar depends on whether the *blood sugar* is below or above a certain *threshold value* This threshold value is influenced by insulin and by the secretion of the *anterior pituitary* when the supply is deficient or the pituitary secretion is excessive, the threshold is *raised*, with the result that the liver pours sugar into the blood and a state of "*diabetes*" is produced, when the supply of insulin is excessive or the pituitary secretion is diminished, the threshold is lowered, the liver removes sugar *from* the blood, and hypoglycæmia results The conception we have been developing in these lectures regards hepatic function as a process adjusted to the needs of the tissues for sugar and subserving the definite object of maintaining the requisite *head of pressure* of blood sugar The *homeostatic* theory, on the other hand, regards the blood sugar level as an *expression of activity* of the liver and this *activity* as being determined not by the needs of the tissues *for carbohydrate* but by the *particular state* of the liver at *any one time* Since the liver plays such an *important* part in *carbohydrate metabolism*, the homeostatic theory *naturally offers* many convenient *explanations* of this aspect of metabolism, but it fails completely to account for the observed *correlations of hepatic functions* with *utilisation of sugar* by the peripheral tissues As an example of this failure the effect of *starvation* may be quoted Starvation causes the blood-sugar tolerance curve to rise to high levels, utilisation of sugar by the *peripheral* tissues normally increases with the height of the blood sugar, yet *after starvation* the normal effect of *glucose in increasing* the oxidation of carbohydrate is greatly diminished, and according to Mann [91 92] and Drury,[36] though not to Soskin and Murphy,[123] in starvation carbohydrate utilisation by the peripheral tissues is *impaired* Again, according to this theory, hypophysial extracts lower the *threshold* at which the liver secretes sugar into the blood, but an explanation is also required of why the same extracts *simultaneously* inhibit insulin action *in the peripheral* tissues *It appears* that, although the homeostatic theory offers many reasonable explanations of hepatic *functions* considered as a *self contained* phenomenon, it does not throw any light on the *relation* of this function to carbohydrate *metabolism* as a whole

Before leaving the question of the rôle of the liver, attention must be drawn to some remarkable *experiments* which may ultimately prove of great importance Markowitz, Mann, and Bollman [86] have shown that after total removal of the liver there is a steady decline in muscle glycogen, and that, although *partially hepatectomised animals readily form muscle-glycogen*, totally hepatectomised dogs do not do so unless relatively enormous quantities of insulin and glucose are injected. They have also shown that insulin action is normal shortly after hepatectomy but may be completely abolished several hours later In rabbits in which the liver was excluded without anæsthesia I have confirmed this fall in muscle-glycogen, and I have also found *impairment* of insulin action in animals from which the liver had been excised This work *suggests* the possibility that the liver is requisite for effective insulin action in the peripheral tissues, and in this connexion it may be recalled that *numerous cases of diabetes*

mellitus which have shown a high grade of insulin resistance have been cases complicated by disease of the liver.[4 37 109 114 130] Impressed by these observations and by experiments indicating that insulin action in the peripheral tissues varied in different circumstances I suggested that the liver might secrete a substance which activated insulin.[59 60] This suggestion still stands and has recently been supported by Krebs's observations [82] that insulin is susceptible of activation

PANCREATIC DIABETES AND INSULIN ACTION

After removal of the pancreas from an animal a syndrome develops which is closely similar to human diabetes mellitus. The blood-sugar level rises and glycosuria is produced. The excessive breakdown of body protein is shown by an increased excretion of urinary nitrogen, and the excessive utilisation of fat by ketonuria.[126] All these findings can be diminished by hypophysectomy, and all, except possibly the increased excretion of nitrogenous bodies in the urine, can be induced in the normal animal by extracts of the anterior-pituitary gland.[72 73 117] Removal of the liver from the depancreatised dog leads to a fall of blood-sugar,[95] of urinary nitrogen, and of ketonuria, and in the normal animal it prevents the effects of pituitary extracts.[73] Thus the liver is the seat of the positive reactions to pancreatectomy—namely, hyperglycæmia,[95] increased breakdown of body protein,[91] and production of ketone bodies [21 102]—and this response of the liver is facilitated by the secretion of the anterior hypophysis. These reactions are called forth by deprivation of insulin, and administration of insulin restores the metabolism of the depancreatised dog to normal. Under its action the blood-sugar falls to normal levels, glycosuria and ketonuria disappear, and the excessive excretion of nitrogen in the urine diminishes. At the same time dietary carbohydrate is retained in the body, ingested protein is no longer hastily broken down to glucose, and the disproportionate utilisation of fat ceases But to prevent the return of the diabetic syndrome insulin must be given in adequate and regular doses. The necessity for an adequate supply of insulin must be clear to every physician who has balanced a diabetic patient. The presence of a regular supply of pancreatic insulin in the healthy subject is indicated by the relatively rapid appearance of hyperglycæmia after pancreatectomy [95] and by contrasting the irregular control of the blood-sugar, achieved by two daily injections of insulin, in the depancreatised animal with the steady control which follows the establishing of a pancreatic graft.[47] To preserve normal metabolism a regular and adequate supply of insulin must be maintained, and this implies that in the course of metabolism insulin is destroyed

The mechanism of insulin action within the individual cell is still unknown, and even on questions of its general effect within the body controversy still exists. Some workers still hold to the opinion that after pancreatectomy the ability of the animal to utilise carbohydrate is unimpaired and regard diabetes mellitus as due primarily to overproduction of sugar. Since this point is of such fundamental importance, it is necessary to indicate the oversight which has led to this opinion. Lusk [87] established that in diabetic animals the respiratory exchange was theoretically compatible with the idea that such animals had lost the power to use glucose; but, since this interpretation of his results depends on the assumption, now being challenged, that animals cannot change fat into carbohydrate, his conclusions are not universally accepted. Evidence that the peripheral tissues of the depancreatised animal can use some glucose is provided by the rapid decline of the blood-sugar that follows hepatectomy in the depancreatised animal,[95] and this evidence has been supported by the demonstration that hypophysectomy in the depancreatised animal partially restores the animal's power to oxidise carbohydrate.[13 72 73 74 126] The dependence of this peripheral utilisation of sugar on the blood-sugar level has been demonstrated by Soskin and Levine,[126] who have shown that in eviscerated animals the rate at which the peripheral tissues use injected glucose is proportional to the height of the blood-sugar, and further that in such preparations made from depancreatised dogs the rate of sugar utilisation, at blood-sugar levels characteristic of the depancreatised animal, is of the same degree as occurs at normal blood-sugar levels in the preparations made from normal animals In view of this evidence the original idea that the depancreatised animal has completely lost the power to utilise carbohydrate cannot be maintained, but this new evidence does not permit the assumption that the power to utilise glucose is unimpaired. The fact that the most characteristic action of insulin is to accelerate removal of sugar from the blood by the peripheral tissues [18 91 94] in itself suggests that in the depancreatised animal the ability of the peripheral tissues to do this would be reduced. So long ago as 1912 it was shown by Knowlton and Starling [81] that the hearts of diabetic dogs used less sugar than the hearts of normal dogs, and it has since been shown that the same is true of other tissues [88 111] Many of Lusk's experiments are acceptable on the basis that in diabetes utilisation of sugar, although not lost, is impaired. The observation that in eviscerated normal animals hyperglycæmia accelerates the utilisation of carbohydrate, whereas in eviscerated diabetic animals with the same degree of hyperglycæmia the utilisation of carbohydrate is not increased, demonstrates that in the latter animals under these conditions peripheral utilisation is impaired.[126] The most probable explanation of these findings seems to be that the tissues of the body have an inherent capacity to utilise sugar at a slow rate, but that, when the blood-sugar level is within normal limits, their capacity to utilise carbohydrate at a normal or rapid rate depends on an adequate supply of insulin. The whole controversy that has centred round the two rival theories of diabetes—the "overproduction theory" and the "under-utilisation theory"—appears to have arisen because it has not been realised that there are mechanisms in the body which can do much to mitigate the effects of *impaired* ability to utilise carbohydrate The opposing ideas, either that in pancreatic diabetes the power to utilise carbohydrate is lost or that it is unimpaired, are both unable to explain large numbers of established facts; but, so far as I am aware, there are no facts incompatible with the hypothesis that in pancreatic diabetes the utilisation of carbohydrate is impaired, but that this impairment is largely compensated by adequate elevation of the head of pressure of sugar in the blood with consequent acceleration of carbohydrate utilisation

Naturally the different conceptions of the nature of pancreatic diabetes have led to different views on the function of insulin Those who hold the view that diabetes results from unchecked overproduction of sugar by the liver see in insulin the agent which checks this excessive activity on the part of the liver; those who hold that diabetes results from impaired

ability of the tissues to utilise carbohydrate see in insulin the factor which restores this impaired ability to normal The action of insulin in directly accelerating the utilisation of sugar by the peripheral tissues has been established beyond any doubt The evidence that insulin acts directly on the liver is at best slender [7 108] The view that it does so appears to be simply a special explanation of the observation that after administration of insulin to depancreatised animals the rate of formation of sugar by the liver is retarded This observation appears to be more logically explained as the result of insulin removing the necessity for a compensatory rise of blood sugar and thus allowing the rate of sugar formation by the liver to decrease to normal levels

DYNAMIC EQUILIBRIUM OF THE BLOOD SUGAR

A brief survey has now been made of some of the main phenomena of carbohydrate metabolism Considered by itself each phenomenon is complicated, and its significance in relation to metabolism as a whole is often not apparent But throughout the whole of normal and abnormal carbohydrate metabolism runs the recurring theme of variations in the head of pressure of blood sugar, and by this theme changes in function of the different organs can be correlated and can be seen to be part of an ordered and useful plan It is appropriate at this stage to attempt this correlation by expressing the observations we have been considering as an inclusive theory

It is suggested that the height of the blood sugar level is the essential mechanism determining the rate of carbohydrate utilisation by the tissues, and that the head of pressure of sugar in the blood is adjusted to that level which, in the particular circumstances, ensures, or comes nearest to ensuring, an adequate rate of carbohydrate utilisation When the ability of the tissues to use carbohydrate is impaired, as by deficiency of insulin, impairment of insulin action, or lack of oxygen, the head of pressure of blood sugar is raised, thereby facilitating the ability of the tissues to use sugar When the ability of the tissues to use carbohydrate is restored or increased, the head of pressure of blood sugar is adjusted to lower levels and excessive utilisation of carbohydrate avoided Thus the head of pressure of sugar in the blood is adjusted at any particular time to the needs of the tissues The liver is the agent of this adjustment When the needs of the tissues are fully satisfied, the liver stores blood sugar as glycogen, when the needs of the tissues are not satisfied, the liver secretes sugar and thus raises the head of pressure of blood sugar If the demands of the tissues are great sugar is secreted at such a rate that the hepatic stores of glycogen are rapidly depleted and the liver is driven to form new sugar from protein and, possibly fat The liver is influenced in these reactions by factors secreted by the anterior lobe of the pituitary gland When these are present in excess, the rate of breakdown of liver glycogen and formation of sugar from non carbohydrate sources is accelerated, when they are absent, these processes are retarded The secretion of these pituitary factors increases in proportion as the needs of the tissues for carbohydrate are unsatisfied

The facts at present available suggest that the ability to utilise carbohydrate is inherent in the tissues, and that this utilisation is facilitated by insulin and retarded by factors secreted by the anterior pituitary gland The efficiency and sensitivity of these mechanisms indicate that the unvarying maintenance of a concentration of sugar in the blood adequate for the needs of the tissues is a point of vital importance in the economy of the body It is difficult to believe that a mechanism for such rapid and sensitive adjustment of the blood sugar level could be necessitated by the needs of such relatively robust structures as muscle, which contain large reserves of carbohydrate and can continue to function for a considerable time, even when totally deprived of their blood supply. It is suggested that the object of this efficient and sensitive mechanism is to ensure to the central nervous system a supply of sugar adequate for its needs. So far as is known, the brain utilises only carbohydrate [7] it contains little or no reserves of carbohydrate,[115] and consciousness depends on an adequate supply of blood sugar, it is as sensitive to deprivation of carbohydrate as it is to deprivation of oxygen The theory may now be illustrated by various examples

In starvation [108] the liver supplies sufficient sugar to the blood to maintain the blood-sugar constant To do this the liver forms sugar from non carbohydrate sources, and this process is revealed by increased excretion of endogenous nitrogen in the urine and by the appearance of ketonuria The new formation of carbohydrate is facilitated by increased secretion of the anterior-pituitary gland, which also economises the utilisation of blood sugar by retarding the action of insulin in the peripheral tissues After some days of starvation the metabolic rate has fallen considerably, and as a consequence the demands of the tissues for carbohydrate from the liver are reduced The formation of sugar by the liver from non-carbohydrate sources therefore diminishes, as is shown by the fall in urinary excretion of nitrogen and by the disappearance of Ketonuria The mechanism of the fall in metabolic rate is not understood

In phloridzin poisoning the head of pressure of blood sugar tends to sink below that adequate for the needs of the body The liver responds by pouring sugar into the blood, which is first derived from the store of liver-glycogen and later from non-carbohydrate sources Secretion of the anterior pituitary gland occurs which retards peripheral utilisation and expedites new formation of sugar

On injection of insulin into a normal animal the removal of sugar to the peripheral tissues, especially the muscles, is increased and the needs of the tissues are satisfied The liver is no longer called on to secrete glucose, and as a result of this and the increased rate of peripheral removal the blood-sugar sinks The fall of the head of pressure of blood-sugar in turn retards peripheral removal of sugar Persistence of the blood sugar at hypoglycæmic levels is prevented by secretion of adrenaline, stimulating hepatic glycogenolysis, and it is possible that the object of this emergency secretion is to restore an adequate supply of sugar to the brain, which, unable to store glucose even under the action of insulin, cannot survive long periods of hypoglycæmia

In pancreatic diabetes the tissues, owing to lack of insulin, cannot utilise carbohydrate sufficiently rapidly for their needs In an attempt to accelerate the utilisation the liver pours sugar into the blood until the head of pressure of blood-sugar reaches levels which either satisfy the needs of the tissues or cannot be increased Since the demand for sugar is great, the store of liver-glycogen is rapidly exhausted and, to maintain the flow of sugar into the blood, the liver is driven to manufacture sugar from non carbohydrate materials The concomitant increased secretion by the pituitary gland facilitates the new formation of sugar by the liver but at the same time retards still further the utilisation of glucose by the tissues If now the pituitary gland is removed the formation of sugar from non carbohydrate materials

is greatly reduced, and ketone formation diminishes with the result that the danger of fatal ketosis becomes remote. At the same time the retardation of peripheral sugar utilisation is removed, and in consequence the blood-sugar is more adequately utilised. For these reasons the hypophysectomised depancreatised dog, although it still suffers from diabetes in an attenuated form, will eke out its existence for several months.

The mechanism of pancreatic diabetes cannot be left without reference to Allen's classical work upon which the "under-nutrition treatment" of human diabetes was based.[5] He showed that in dogs from which sufficient pancreas had been removed to render them on the verge of diabetes overfeeding precipitated

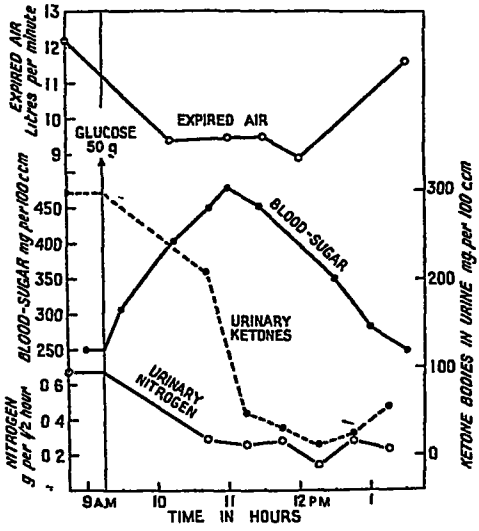

FIG 6—The effect of ingestion of 50 g. of glucose in an untreated diabetic patient. It will be seen that, as the blood-sugar rises, the excretion of nitrogen and ketones in the urine falls [59]

diabetes, whereas with underfeeding diabetes did not develop. The islets of Langerhans in the pancreas remaining in the dogs made diabetic by overfeeding showed typical degeneration.[6] Young has produced permanent diabetes [140] and similar lesions of the pancreas in normal dogs [112] by injecting anterior-pituitary extracts. It is suggested that in Allen's partially depancreatised dogs the high needs of the tissues for sugar, consequent upon overfeeding, called for more insulin than was available from the pancreatic remnant. Consequently the needs of the tissues for sugar were relatively unsatisfied, and in an attempt to remedy this the blood-sugar was raised to high levels and new formation of carbohydrate by the liver was accelerated. To facilitate this process, pituitary factors were secreted in excess and secondarily produced the degeneration of the islet cells, with the result that ultimately permanent diabetes developed. By keeping these dogs in a state of chronic undernutrition this unfavourable sequence of events can be avoided.

The clinical study of human diabetes provides numerous examples of the dynamic equilibrium of the blood-sugar. The two following examples will suffice as illustrations It is a well-known clinical observation that in diabetes mellitus the blood-sugar level rises spontaneously during the night,[54] and, if the patient is receiving insulin during the day, this rise is by contrast all the more striking. During the day relatively adequate utilisation of carbohydrate by the tissues is ensured by the dietary carbohydrate and the insulin which the patient is receiving. In the fast between supper and breakfast the action of the injected insulin wanes, with the result that the ability of the tissues to utilise carbohydrate diminishes, and as a consequence the liver is stimulated to pour sugar into the blood and to increase the head of pressure of sugar in the blood. This spontaneous rise of blood-sugar can be prevented either completely or partially by measures which promote utilisation of sugar by the tissues during the night, such as nocturnal injections of insulin, exercise, or, in favourable circumstances, a carbohydrate meal at midnight before the rise has set in.

The beneficial effect of raising the blood sugar in a human diabetic patient is well shown by the following example.[58]

A young untreated female diabetic was admitted with severe ketosis She was given quantities of water to drink and frequent urine specimens were obtained. When the excretion of ketone bodies and nitrogen in the urine samples had reached a constant level, the patient was given 50 g. of glucose by mouth, but not any insulin. With the consequent rise of blood-sugar the ketonuria and excretion of urinary nitrogen diminished; but, as the blood-sugar fell, the ketonuria and urinary nitrogen excretion rose again (fig. 6).

It is a well-established clinical observation that ketonuria increases with the approach of diabetic coma and diminishes as this danger recedes, and recently Gray has shown that there is a similar change in ketonæmia [50] It appears, therefore, that with the rise of blood-sugar the severity of the diabetes became less, but with the fall of blood-sugar the severity again increased The explanation of this sequence of events seems to be as follows As a consequence of the diminished ability of the tissues to use carbohydrate the liver, in an attempt to compensate this disability, poured sugar into the blood and hyperglycæmia resulted. But the head of pressure of sugar in the blood achieved by the liver was insufficient to accelerate utilisation of sugar by the tissues to a degree which satisfied their needs. As a consequence the demands on the liver continued, with the result that the formation of sugar from non-carbohydrate sources proceeded rapidly and was manifested by ketonuria and increased excretion of nitrogen in the urine At this stage the patient received the glucose With the consequent rise of blood-sugar the tissues received, and therefore used, more carbohydrate, the demands on the liver decreased, and consequently the new formation of sugar by the liver diminished. This was shown by a fall in ketonuria and urinary nitrogen. With the subsequent fall of the blood-sugar the original state re-established itself. The suggestion follows that the reason why a diabetic passes into diabetic coma is primarily because he cannot raise his blood sugar high enough to ensure adequate utilisation of carbohydrate; for, if this object were attained, the excessive metabolism of protein and fat would diminish and ketosis would not develop This suggestion is not incompatible with clinical experience, for it is known that, as a result of giving glucose and insulin, the blood-sugar level after recovery from coma may be higher than when coma was present; nor is it uncommon to see patients up and about and well with blood-sugar values at levels higher than those found in many comatose patients.

CYANOSIS CAUSED BY SULPHONAMIDE COMPOUNDS

BY DAVID CAMPBELL, M.C., M.D. Glasg.
PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS IN THE UNIVERSITY OF ABERDEEN, AND

THOMAS N. MORGAN, M.D. Aberd.
LECTURER IN MATERIA MEDICA IN THE UNIVERSITY, VISITING PHYSICIAN TO THE WOODEND HOSPITAL ABERDEEN, CLINICAL TUTOR AT THE ABERDEEN ROYAL INFIRMARY

CYANOSIS developing during the course of treatment with drugs of the sulphonamide group has been found by Colebrook and Kenny (1936), Paton and Eaton (1937), Discombe (1937), Wendel (1938), Gley (1937), and others to be due to the conversion of part of the circulating hæmoglobin to sulphæmoglobin or to methæmoglobin. Several observers have, however, reported its development in cases where no alteration of the blood pigment could be detected spectroscopically, and where there was no change in the oxygen carrying power of the blood (Colebrook and Purdie 1937, Marshall and Walzl 1937, Cheesley 1938). By way of explanation, some of them have postulated the formation of a coloured aniline derivative in the blood stream (*Young and Wilson* 1926–27, Ottenberg and Fox 1938, Marshall and Walzl 1937).

During an extensive clinical use of *p* aminobenzenesulphonamide and 2 *p* aminobenzenesulphonamido pyridine we have found that cyanosis of varying intensity has been a frequent symptom, but we have always been able to account for it either from the clinical state of the patient or by careful spectroscopic examination of the blood. In cases treated with *p* aminobenzenesulphonamide the pigment may be either methæmoglobin or sulphæmoglobin but in our experience is more frequently the latter. On the other hand, the pigment formed during treatment with 2 *p* aminobenzenesulphonamidopyridine is practically always methæmoglobin. Of 32 cases of pneumonia treated with this drug methæmoglobin was detected in the blood of 25, and no case of sulphæmoglobinæmia developed spontaneously, despite the fact that no special precautions were taken to avoid purgation or sulphur containing foods.

With the usual type of clinical spectroscope the differentiation between sulphæmoglobin and methæmoglobin is not always easy, because the characteristic absorption bands of both lie in the same vicinity at the red end of the spectrum. The sulphæmoglobin band occupies the wave lengths from 615 μμ to 630 μμ, whereas that of methæmoglobin occupies the wave lengths from 625 μμ to 655 μμ. It is, however, of some importance from the prognostic point of view that the differentiation between the two pigments should be made, because cyanosis due to sulphæmoglobin lasts for several weeks whereas that due to methæmoglobin remains only a few days. In this investigation several types of spectroscopes were employed. It was found that one of small dispersion was the most suitable for detecting absorption bands at the red end of the spectrum. For the accurate measurement of the position of an absorption band a large model Hilger constant deviation spectroscope was used. Quantitative estimations of the meter was used. Quantitative estimations of the absorption of light were made with this instrument together with a Nutting photometer. In some experiments band positions were compared with the Hartridge reversion spectroscope.

In the course of the investigation it became evident that for accurate spectroscopic examination of the blood, particularly for the presence of methæmoglobin, two precautions are necessary:—

(1) The blood must be laked with a small volume of water (not more than 1 in 5) so that the pigment may be in a concentrated solution.

(2) The specimen should be examined as soon after withdrawal as possible.

Table I shows the percentage of methæmoglobin which must be present in a mixture with oxyhæmoglobin before its absorption band becomes visible to the eye. These figures were obtained by examining the spectrum through two absorption cells of equal depth (0·5 cm.), one cell containing oxyhæmoglobin and the other methæmoglobin. By varying the proportion of methæmoglobin and oxyhæmoglobin so that the percentage of methæmoglobin was reduced while the total content of blood pigment in the two cells remained constant, the lowest percentage of methæmoglobin which could be detected was determined for different dilutions of blood. It will be seen that in a 1 in 50 dilution of blood the band of methæmoglobin appeared only when 50 per cent. or more of the total pigment was present as methæmoglobin, but that this critical limit was reduced as the strength of the hæmoglobin solution was increased. It will be obvious therefore that, unless the blood is laked with only a small amount of water (not more than 1 in 5) or is examined in a layer several centimetres thick, the presence of methæmoglobin may easily be missed.

TABLE I—METHÆMOGLOBIN

Dilution of blood	Minimal concentration of methæmoglobin producing visible absorption (per cent.)	
1–50	50	Faint line
1–20	30	
1–5	10	

TABLE II—SULPHÆMOGLOBIN

Dilution of blood	Minimal concentration of sulphæmoglobin producing visible absorption (per cent.)	
1–50	10	Faint line
1–20	4	
1–10	2	Well marked line
1–5	0·5	

The same thing is true if a considerable time elapses between the withdrawal of blood and its spectroscopic examination. Fig. 1 shows graphically the absorption coefficients measured at 634 μμ at intervals after withdrawal of a sample of blood from a case of methæmoglobinæmia. The density of the characteristic band diminishes rapidly, in cases where the amount is not large it may be entirely absent in twelve hours. This is probably due to a gradual increase in the pH of the blood, for the characteristic band of methæmoglobin is well seen only in a neutral or acid solution.

These precautions are not so essential in the case of sulphæmoglobin. Table II shows that a 10 per cent. concentration of this pigment can be detected in dilutions of blood as low as 1 in 50, and that in a 1 in 5 dilution a concentration of 0·5 per cent. gives an easily visible line, whereas fig. 1 shows that even thirty hours after the withdrawal of blood from a patient with sulphæmoglobinæmia there is no alteration in the density of the band at 625 μμ.

These observations suggest that the number of cases of cyanosis reported as developing during

sulphonamide treatment, without demonstrable sulphæmoglobinæmia or methæmoglobinæmia and without obvious cause, might be considerably reduced if samples of blood were examined promptly and in

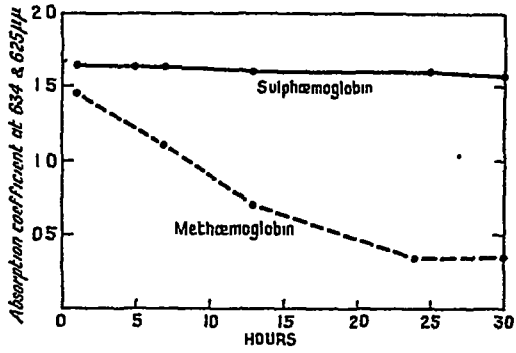

FIG 1—The variation in the absorption coefficients in the same sample of blood from a case of sulphæmoglobinæmia and from a case of methæmoglobinæmia The density of the band diminished rapidly in the case of methæmoglobin but remained unchanged in the case of sulphæmoglobin

concentrated solution, and that it may be unnecessary to speculate on the possibility of any coloured derivative of aniline being the causal agent of the symptom. Wendel (1938), employing a technique somewhat similar to ours, has reported that he can demonstrate the presence of methæmoglobin in every case receiving sulphonamide where the blood concentration of the drug is over 4 mg. per 100 c cm., and our experience agrees with this observation.

TREATMENT OF CYANOSIS

Although the onset of cyanosis is usually without serious significance, it is alarming and may have a disturbing psychological effect on the patient and his relations Further, as Discombe (1937) has pointed out, in conditions of severe anæmia or in serious pulmonary disease, such as lobar pneumonia, a reduction in the oxygen capacity of the blood, consequent on the development of methæmoglobinæmia or of sulphæmoglobinæmia, may be sufficient to cause dangerous anoxæmia and thus aggravate considerably the disability of the patient Any method of prevention or treatment of this symptom, therefore, would be a welcome adjunct where the prolonged administration of drugs of the sulphonamide group is necessary. The use of methylene-blue in the treatment of methæmoglobinæmia, originally suggested by Hauschild (1936), has been advocated by Wendel (1937) and favourably reported on by Hartmann et al (1937), although it constitutes a therapeutic measure of some importance, its scope in the prevention and treatment of the various abnormalities of blood pigment produced by sulphonamides has not been fully investigated. We decided, therefore, to try to assess its therapeutic value in the treatment of methæmoglobinæmia and sulphæmoglobinæmia

Blood for examination was prepared in the following way: 2 c cm. of blood was made up to 10 c.cm. with distilled water, and 1 c.cm. of saponin solution was added and the mixture centrifuged at 3000 revolutions a minute. Quantitative estimations of methæmoglobin were made spectrophotometrically. The absorption coefficient of each sample of blood was measured throughout the red end of the spectrum at intervals of 5 μμ. By comparing these at the wavelength where the absorption band is at its maximal density (634 μμ for methæmoglobin and 625 μμ for sulphæmoglobin) it was possible to represent graphically variations in the methæmoglobin and sulphæmoglobin content of the blood.

METHÆMOGLOBINÆMIA

In the following cases of pneumonia methæmoglobinæmia developed during treatment with 2 *p* aminobenzenesulphonamidopyridine and the effect of methylene-blue is illustrated

CASE 1.—A man, aged 38, was admitted suffering from lobar pneumonia with involvement of the right middle lobe. He was given 2-*p*-aminobenzenesulphonamidopyridine in doses of 6 g. daily. Cyanosis due to methæmoglobinæmia appeared on the second day of treatment and was intense on the third day. Methylene-blue 350 mg. was then administered by intravenous injection. Within ten minutes the leaden-blue colour of the mucous membrane and ears had given place to a bright healthy pink, and no methæmoglobin could be detected in the blood. Methæmoglobinæmia did not recur, although treatment with the drug was continued till the sixth day (fig. 2).

CASE 2.—A man, aged 42, was admitted to hospital suffering from lobar pneumonia involving the right lower lobe. He received daily 6 g. of 2-*p*-aminobenzenesulphonamidopyridine in divided doses of 1 g. every four hours. The blood on the third day showed the presence of methæmoglobin, and on the fourth day cyanosis was obvious After the intramuscular injection of 400 mg. of methylene-blue the methæmoglobinæmia disappeared. Treatment with the sulphonamide was not interrupted, and methæmoglobinæmia reappeared on the following day A daily dose of 1 g. of methylene-blue was then given by mouth for the next three days, and methæmoglobin disappeared from the blood and did not recur (fig. 3).

CASE 3.—A youth of 18 was admitted suffering from lobar pneumonia with involvement of the left

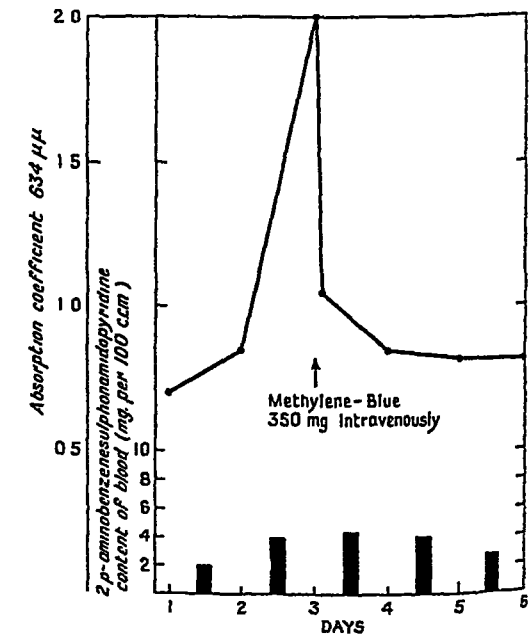

FIG 2—The effect of a single intravenous injection of methylene-blue in causing the disappearance of methæmoglobin in case 1

lower lobe. He did not respond to the administration of the usual daily dose of 6 g of 2-*p*-aminobenzenesulphonamidopyridine, and the estimation of the amount of the drug in the blood-stream revealed

very low values It was assumed that the drug was poorly absorbed, and the dose was increased by 2 g daily with a consequent increase in the concentration of the drug in the blood Coincidentwith this, methæmoglobinæmia appeared, and three days later cyanosis was intense Methylene-blue 150 mg was injected intravenously and caused such a rapid disappearance of the methæmoglobin that it could not be detected in the blood five minutes after the injection (fig 4)

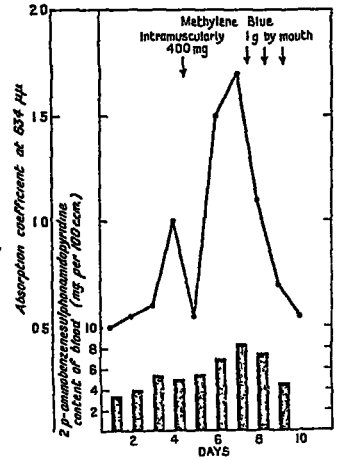

FIG 3—The action of methylene blue by intramuscular injection and by mouth in case 2

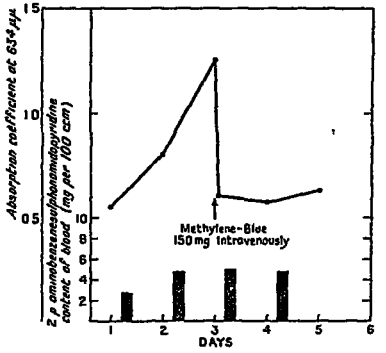

FIG 4—The effect on the absorption coefficient at 634 μμ of 150 mg of methylene blue given by intravenous injection in case 3

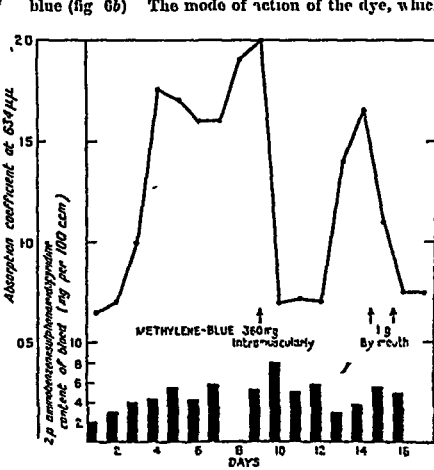
CASE 4 —A man, aged 38, was admitted to hospital suffering from lobar pneumonia Physical examination showed consolidation of the right lower lobe He received 2-*p* aminobenzenesulphonamidopyridine in doses of 6 g daily Cyanosis developed on the third day, and methæmoglobin was demonstrated in the blood This increased in intensity, and on the ninth day 360 mg of methylene blue was administered by intramuscular injection On the following day the cyanosis had entirely disappeared, and methæmoglobin could no longer be detected in the blood The administration of the sulphonamide was continued Methæmoglobin reappeared on the twelfth day, and on the fourteenth day cyanosis was again obvious He then received 1 g of methylene-blue daily by mouth for two days and at the end of that time the cyanosis had disappeared entirely The blood iron was estimated daily by the method of Wong and remained constant It must be assumed, therefore, that the disappearance of the methæmoglobin was due to conversion of this pigment to hæmoglobin and not to its destruction or excretion Fig 5 shows graphically the variation in the absorption coefficient of the blood at 631 μμ throughout the period of investigation

It can hardly be argued that the results obtained in these cases were due to a natural and spontaneous remission in the severity of the cardinal symptom, because we had previously found that, when methæmoglobinæmia developed during treatment with 2 *p* aminobenzenesulphonamidopyridine, the pigment could be detected in the blood four or five days after all trace of the drug had disappeared from the blood stream It is justifiable, therefore, to conclude that methylene blue actively converts methæmoglobin into hæmoglobin

It is of interest to record that methylene blue has a similar action on the methæmoglobinæmia produced by the administration of nitrites If 100 mg of sodium nitrite per kg of body weight is injected intravenously into a rabbit, well marked methæmoglobinæmia appears within half an hour If at this stage an intravenous injection of 10 mg per kg of methylene blue is given, methæmoglobin disappears from the circulation within five to ten minutes (fig 6*a*) Furthermore, the production of methæmoglobinæmia by sodium nitrite can be prevented by the simultaneous injection of methylene blue (fig 6*b*) The mode of action of the dye, which



Absorption coefficient at 634 μμ

METHYLENE-BLUE 360 mg intramuscularly
1 g By mouth
DAYS

FIG 5—The action of methylene blue in causing the disappearance of methæmoglobin from the blood-stream when given by intramuscular injection and by mouth in case 4

in the tissues is reduced to the leuco compound, is presumably one of oxidation-reduction, the ferric iron of hæmoglobin being altered to the ferrous state.

The dye, as we have shown, is active when given by mouth. It is also slowly excreted After the oral administration of 1 g it can be detected in the urine for three or four days. A prolonged effect can

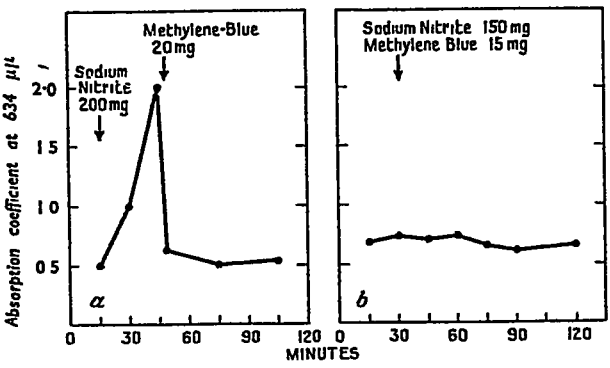

FIG 6—(*a*) The effect of methylene-blue in causing the disappearance of methæmoglobinæmia induced by the injection of sodium nitrite in a rabbit. (*b*) The effect of the simultaneous administration of methylene-blue and sodium nitrite No methæmoglobin appeared in the blood-stream.

therefore be obtained by giving it by mouth in divided doses several times a day In view of its action in preventing methæmoglobinæmia, it is well worth while considering the advisability of giving it as a routine along with 2-*p*-aminobenzenesulphonamidopyridine in the treatment of pneumonia and other infective conditions.

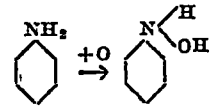
SULPHÆMOGLOBINÆMIA

In view of the results obtained in methæmoglobinæmia, the efficacy of methylene-blue was tried out in two cases of sulphæmoglobinæmia which developed after the administration of *p*-aminobenzenesulphonamide The dye was given intravenously and by mouth but was without effect Fig 7 shows that when 200 mg of methylene-blue was injected intravenously, the absorption coefficient at 625 μμ remained constant throughout the period of observation The oral administration of 0·5 g. thrice daily over a period of three days was also ineffective in altering the abnormal blood pigment

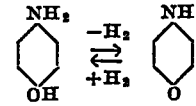
We found also that methylene-blue did not prevent the development of sulphæmoglobinæmia when administered along with *p*-aminobenzenesulphonamide. Two volunteers were given 1 g. of the sulphonamide three times daily, 4 g of confection of sulphur each morning, and 1 g. of methylene-blue daily in three divided doses In both cases the typical band of sulphæmoglobin appeared in the blood within forty-eight hours and was dense on the fourth day.

The mode of formation of sulphæmoglobin after the administration of sulphonamides has not been satisfactorily explained. Archer and Discombe (1937) have reported experiments which suggest that sulphonamide, by virtue of the C_6H_5N group, sensitises hæmoglobin to the action of hydrogen sulphide. We have been unable to find any evidence of a sensitising effect in experiments in vitro, though we have confirmed their results regarding the ease with which sulphæmoglobinæmia can be induced in man when sulphur is given along with *p*-aminobenzenesulphonamide, and we have found that the same thing may happen if 2-*p*-aminobenzenesulphonamidopyridine and sulphur are administered together.

According to Ellinger (1920) and Lipshutz (1920) aniline derivatives are oxidised in the blood to phenylhydroxylamine—



and Gley (1937) has suggested that it is this compound which is responsible for the formation of methæmoglobin and, in the presence of sulphide, of sulphæmoglobin He has shown that in vitro the addition to blood of a substance containing the hydroxylamine group results in the formation of methæmoglobin, but that, if a trace of hydrogen sulphide is present, sulphæmoglobin is formed Rimington (1939), however, thinks it unlikely that hydroxylamine is the methæmoglobin-forming substance, because of the ease with which it is oxidised in the tissues to azoxybenzene, and believes that it is the formation of *p*-aminophenol which is the important factor, because this substance is readily oxidised in the tissues to *p*-iminoquinone—



He points out, further, that this oxidation is reversible, and accordingly *p*-aminophenol will be able to form many times its equivalent of methæmoglobin

That this is a possible explanation of the formation of sulphæmoglobin as well is shown by the following experiment.—

To 5 c cm. of laked blood 3 drops of a saturated solution of *p*-aminophenol was added. Spectroscopic examination at the end of ten minutes showed the presence of methæmoglobin.

To another 5 c.cm. of the same laked blood 3 drops of a weak solution of hydrogen sulphide was added; in ten minutes no alteration in the blood pigment had taken place.

To a third 5 c cm. of the same laked blood 3 drops of a weak solution of hydrogen sulphide and 3 drops of *p*-aminophenol solution were added. At the end of five minutes a dense band of sulphæmoglobin was present.

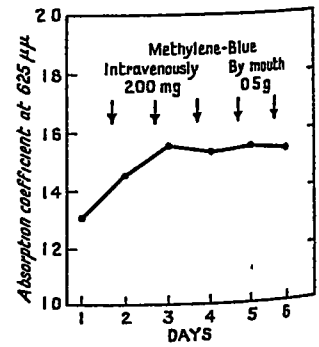


FIG 7—The action of methylene-blue by intravenous injection and by mouth in an established case of sulphæmoglobinæmia. No alteration in density of the absorption band took place.

It should be noted that the ease with which substances with a free amino group form sulphæmoglobin in the presence of sulphide is peculiar, because other agents which in vitro alter hæmoglobin to methæmoglobin—e g, sodium nitrite, potassium ferricyanide, and potassium permanganate—if added to blood containing hydrogen sulphide, produce sulphæmoglobin much more slowly

It is possible, therefore, to explain the specific action of aniline derivatives in forming sulphæmo

globin if we assume that they are changed in the tissues to *p* aminophenol, which leads primarily to the formation of methæmoglobin, but that, if sulphide is present during this process, the sulphide combines with the iron of hæmoglobin when in the ferric state and gives rise to sulphæmoglobin If this explanation is correct, the fact that methylene blue will not, as we have shown, prevent sulphæmoglobinæmia suggests that the dye does not really inhibit the formation of methæmoglobin but simply changes it fairly rapidly back to hæmoglobin, so that the abnormal pigment cannot accumulate in the circulation

CONCLUSIONS

(1) When examining blood spectroscopically for methæmoglobin, it is essential that the sample should be laked with only a small volume of water and examined soon after withdrawal Otherwise the presence of the pigment may not be detected

(2) In cyanosis developing during the therapeutic use of 2 *p* aminobenzenesulphonamidopyridine and *p* aminobenzenesulphonamide, where there is no other obvious cause, careful spectroscopic examination of the blood always demonstrates the presence of either methæmoglobin or sulphæmoglobin

(3) In methæmoglobinæmia, whether produced by 2 *p* aminobenzenesulphonamidopyridine or by sodium nitrite, methylene blue is effective in causing the rapid disappearance of the cyanosis by converting methæmoglobin to hæmoglobin

(4) The dye is active when given intravenously, intramuscularly, or by mouth

(5) It is suggested that the routine employment of methylene blue in conditions calling for the prolonged administration of 2 *p* aminobenzenesulphonamidopyridine may be a useful measure in preventing cyanosis

(6) Methylene blue has no effect in preventing or modifying the cyanosis of sulphæmoglobinæmia

"We know that a mixture of blood is good for the race A periodic stirring of the cauldron mixes the ingredients and brings out qualities of mind and body which tend to stagnate, if left undisturbed too long The sack of Constantinople was followed by the renaissance The sack of Constantinople was followed by the renaissance of our cities be followed So, I hope, may the evacuation of our cities be followed by a re-awakening of rural England and the dawn of a new era of living planned on healthier and more spacious lines than those to which so many of our countrymen have become accustomed for there is little doubt that many of the refugees will never return"—Dr W A Lethem, medical officer at the Ministry of Health, speaking at the Royal Sanitary Institute Health Congress at Scarborough on July 5, 1939

EFFECT OF SULPHANILAMIDE ON THE BLOOD IN SCARLET FEVER

By JANE O FRENCH, M D Glasg, D P H, D R C O G

ASSISTANT MEDICAL OFFICER IN THE CITY OF COVENTRY PUBLIC HEALTH DEPARTMENT LATE RESIDENT ASSISTANT PHYSICIAN AT RUCHILL FEVER HOSPITAL, GLASGOW

AMONG all the enthusiastic and conflicting reports on the value of the sulphanilamide class of drugs one fact stands out clearly unpleasant and even fatal reactions have followed their use These effects are very variable in their nature, incidence, and severity Blood disorders take a high place among the unfortunate sequelæ of sulphanilamide therapy Ten cases of agranulocytosis have been recorded Plumer (1937), Borst (1937), Young (1937), Model (1937), Schwartz, Garvin, and Koletsky (1938), and Berg and Holtzman (1938) have reported fatal cases, and Jennings and Southwell Sander (1937), Tourtune, Durel, and Baudouin (1937), and Allen and Short (1938) reported cases in which recovery ensued Some observers have noted a depression in the leucocyte count not amounting to agranulocytosis (Johnston 1938) Several cases of acute hæmolytic anæmia following sulphanilamide therapy have been recorded (Harvey and Janeway 1937, Kohn 1937, Long and Bliss 1937, Wood 1938) and three of non hæmolytic anæmia (Jennings and Southwell Sander 1937)

The effect of sulphanilamide on the leucocytes has as yet received relatively little attention either from the experimental or the clinical aspect Marshall, Cutting, and Emerson (1938) found no change in the blood picture of four rabbits and two dogs after the administration of sulphanilamide Bigler, Chilton, and Werner (1938), who investigated the leucocyte response to sulphanilamide in 33 patients before, during, and after treatment, concluded that sulphanilamide seemed to cause a depression of the white blood cells, even to a point at which leucopenia developed, but that agranulocytosis did not develop with this depression of leucocytes Britton and Hawkins (1938) investigated the action of sulphanilamide on the leucocytes of 50 ambulant female patients Leucocyte counts of less than 5000 per c mm were recorded in 18 of these, and the authors considered that there was a polymorphonuclear *leucopenia in 16 per cent of their cases* The lymphocytes remained normal throughout, but monocytosis developed in 44 per cent of the patients and eosinophilia in 20 per cent Campbell (1938) found no change in the erythrocyte, hæmoglobin, and total leucocyte counts in the cases investigated by him He found that moderate doses of sulphanilamide stimulated a slight rise in the reticulocyte level, which is not necessarily associated with anæmia or leucopenia

Method of Investigation

During 1937 and 1938 a controlled series of 340 *cases of scarlet fever was treated with sulphanilamide* at Ruchill Fever Hospital, Glasgow Half of the patients received sulphanilamide treatment, while the remaining 170 were not so treated allocation to each form of treatment being determined solely by order of admission to hospital Observations were made on the blood counts of patients in this series It is not intended here to discuss the therapeutic effect of the substances used but merely to record the effect of sulphanilamide on the total blood count and on the differential blood count Of the 444

leucocyte counts made approximately half, and of the 56 differential blood-counts 30, were in patients treated with sulphanilamide. The results of these investigations are described and discussed

The amount of sulphanilamide given was large, and treatment was continued during the entire period of four weeks which constitutes the average time of detention of scarlet-fever patients in hospital The dose was as follows —

Patients 5 years of age or older were given 1 g. four-hourly—i.e., 5 g. daily—for the first fourteen days in hospital and then 1 g. thrice daily—i.e., 3 g. daily—for fourteen days. The average total dose was 112 g

Patients under 5 years of age were given 0·5 g. four-hourly—i.e., 2·5 g. daily—for the first fourteen days in hospital and then 0·5 g. thrice daily—i.e., 1·5 g. daily—for fourteen days. The average total dose was 56 g.

Concentrated scarlet-fever antitoxin was given to any patient who was thought to require it, irrespective of whether that patient was going to have sulphanilamide or not Of the 340 patients 269 were treated with serum The average dose was 20 c.cm., the least 10 c.cm., and the greatest 40 c.cm Of the patients receiving sulphanilamide 135 (79·4 per cent.) received serum, and of the controls 134 (78·8 per cent.) received serum. The patients showed an even distribution in respect of age-incidence, sex-incidence, and complications present on admission and developing later (French, to be published)

Results

The results recorded cannot be considered directly comparable with those of others who have made observations on the effect of sulphanilamide on the blood. The patients were all suffering from a condition which can per se cause a leucocytosis, and many had late complications which would tend to maintain that leucocytosis No attempt was made to examine the blood of selected cases systematically; the leucocyte counts were made at random, and it was hoped that an even distribution in respect of treatment, day of illness, and other factors would result from this method of selection, as in fact it did. The counts relate to scarlet-fever patients at all stages of the disease within the first four weeks, and there are a few observations made on patients after that period. It will be observed later that the leucocyte counts in the latter group are higher than normal. These patients all had some complication responsible for their longer period of detention in hospital and this complication probably caused the leucocytosis The action of sulphanilamide on the blood in this series of cases can only be studied by comparing the sulphanilamide cases with the control cases at the same period of the illness This was done and the results of the total leucocyte count, the differential leucocyte count, the red-cell count, and the percentage of hæmoglobin are shown.

TABLE I—TOTAL LEUCOCYTE COUNTS

	Sulphanilamide group		Control group		Difference (per cent.)	Standard error of difference
	No.	Per cent.	No.	Per cent.		
Total leucocyte counts made	211	100	233	100	—	—
Highest recorded count per c.mm	43,800		52,400		—	—
Lowest recorded count per c.mm	5200		7400		—	—
Counts under 5000 per c.mm	None		None		—	—
Counts between 5000 and 10,000 per c.mm	34	16·1	22	9·4	6·7	3·170
Counts between 5000 and 10,000 per c.mm in first week of illness—i.e., during period of high sulphanilamide dosage	15	23·0	5	6·3	16·7	5·912

TOTAL LEUCOCYTE COUNT

Table I shows the salient features of the observations on the total leucocyte count, fig. 1 the average leucocyte count at weeks in the form of a graph; and fig. 2 the average leucocyte count at three-day intervals in the form of a graph There are some statistically significant differences between the average total leucocyte counts in the control group and those in the sulphanilamide group, and all the available evidence points to a constant slight depression in the white-cell count in the cases treated with sulphanilamide A much higher percentage of counts in the sulphanilamide group did not show a leucocytosis, and this difference was very obvious indeed in the first week of the illness, when leucocytosis might be expected in practically all instances In no case did this depression of the white-cell count amount to a leucopenia, the estimations being well above the normal upper limit of 10,000 leucocytes per c.mm in a large majority of the cases investigated.

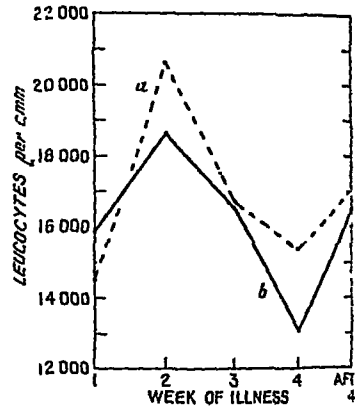

FIG 1—Mean leucocyte count at weekly intervals in scarlet fever: (*a*) patients not treated with sulphanilamide. (*b*) patients treated with sulphanilamide

DIFFERENTIAL LEUCOCYTE COUNT

Polymorphonuclear neutrophil leucocytes.—Since sulphanilamide is believed to have a toxic action on the bone-marrow, neutropenia was particularly sought for When the polymorphonuclear neutrophil cells were less than 60 per cent of all the white cells, this was considered to be below normal, and the following were the percentages in each group which gave this figure.—

Sulphanilamide cases	33·3 per cent
Control cases	15·3 "
Difference	18·0 "
Standard error of difference	11·31 "

Although this difference is statistically insignificant there appears to be some ground for the belief that sulphanilamide has a depressant action on the neutrophil polymorphs and hence on the bone-marrow

Large and small lymphocytes.—Although variations in the number of the lymphocytes are usually relative and depend merely on the number of polymorph cells, absolute increase is not unknown. Attention was paid to the lymphocytes in the following manner Cases in which the total leucocyte count was 10,000 or less per c.mm were ignored, for in them any percentage increase in the lymphocytes was probably due to a diminished polymorph count. All cases in which the total leucocyte count was 10,000 or more

per c mm , and in which the lymphocytes numbered 30 or more per cent , were considered to represent a true lymphocytosis This was found in 1 case in the control group and in 7 in the sulphanilamide group I do not know what is the significance of this finding, if indeed there is any Some of these cases with polymorphonuclear neutrophil counts of less than 60 per cent were included in those considered to have a neutropenia If the condition was to be regarded as a lymphocytosis this should not have been done, but it is difficult to know how it should be classified Wylie (1929) found a constant increase in the percentage of small lymphocytes in scarlet fever up to the seventh day of illness A brief summary of the counts showing lymphocytosis is given in table II

Mononuclear leucocytes —No significant change in the proportion of mononuclear leucocytes was observed in the cases examined The upper limit of normality (7 5 per cent of all white cells) was exceeded in 20 per cent of counts in the control group and in 15 3 per cent in the sulphanilamide group The difference is 4 7 per cent and the standard error of the difference 10 17

Eosinophil leucocytes —Of the control group 23 1 per cent of those examined were found to have

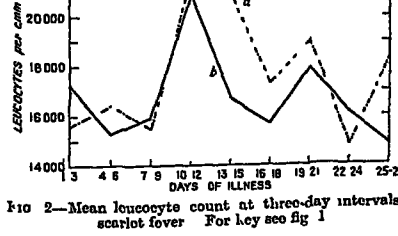

FIG 2—Mean leucocyte count at three-day intervals in scarlet fever For key see fig 1

more than 4 per cent of eosinophil leucocytes, the corresponding figure in the sulphanilamide group being 20 per cent The difference is 3 1 per cent and the standard error of the difference 11 01 The highest recorded eosinophil count was 16 5 per cent in a man, aged 23, who was in the control group and was treated with serum The count was recorded on the fifth day of a moderately severe uncomplicated attack of scarlatina simplex

TABLE II—CASES SHOWING LYMPHOCYTOSIS

	Total white cell count per c mm	Neutrophil polymorphs (per cent)	Lymphocytes (per cent) Large	Small	Total
Case in control group	19 700	58 0	13 5	22 0	35 5
Cases in sulphanil amide group	11 200	60 5	11 0	21 0	32 0
	10 700	55 5	11 0	23 0	34 0
	10,300	51 0	7 0	37 5	44 5
	12 400	69 5	7 5	23 0	30 5
	18,300	58 0	3 5	32 0	35 5
	12 400	40 0	17 5	31 0	48 5
	10 500	59 5	0 5	25 0	34 5

Three days later the eosinophil count had dropped to 5 5 per cent There was no history of asthma or other allergic manifestations

RED CELL COUNT

Sulphanilamide appeared to have a slightly depressant effect on the red blood cells The average counts recorded in each week of illness in the two groups are shown in table III

HÆMOGLOBIN

Sulphanilamide was found to have no apparent effect on the hæmoglobin The average readings recorded in each week of illness in the two groups are shown in table IV

TABLE III—RED CELL COUNTS IV—HÆMOGLOBIN

Week of illness	Red blood-cells per c mm		Hæmoglobin (Sahli) (per cent)	
	Sulphanil amide group	Control group	Sulphanil amide group	Control group
1	5,180,000	5,320,000	101 0	97 4
2	4,090,000	5 323,000	90 1	95 3
3	4 893,000	4,490,000	91 6	86 0
4	4,958,000	5,315,000	97 0	87 0

Discussion

These observations show that sulphanilamide had little deleterious effect on any element of the blood except the polymorphonuclear leucocytes In the patients treated with sulphanilamide a slight but constant depression of the total white cell count was observed at all periods of scarlet fever, especially in the first week Differential counts showed that this was due to a diminution in the neutrophil polymorphs Although this depression never amounted to an actual leucopenia, it is easy to imagine that in a patient with a grave infection, in whom the marrow is already depressed, the administration of sulphanilamide may have the unfortunate effect of bringing about the serious state of agranulocytosis It seems very significant that, in the sulphanilamide group, 23 per cent of those examined in the first week of illness did not show a leucocytosis, whereas the corresponding figure in the control group was only 6 3 per cent After the first week the occurrence of leucocytosis is too variable for its absence to have the same significance

I am greatly indebted to Dr W M Elliott, physician-superintendent of Ruchill Fever Hospital, for permission to publish these results

FRACTURED PATELLA TREATED BY EXCISION OF THE FRAGMENTS

By HAROLD DODD, Ch M. Lpool, F.R.C.S.

SURGEON TO KING GEORGE HOSPITAL, ILFORD, AND TO THE ROYAL HOSPITAL, RICHMOND, ASSISTANT SURGEON TO THE LONDON HOMŒOPATHIC HOSPITAL

WHEN Ralph Brooke advocated treatment of the fractured patella by excision of the fragments in 1937, the surgical world was startled. It caused a similar effect on Prof. Hey Groves, the editor of the *British Journal of Surgery*, for he travelled to see Brooke's actual patients and then, stimulated to study the matter with Prof. Whitnall, he wrote a note on the anatomy and mechanics of the patella confirming the soundness of the principle (Groves 1937) Since then Gordon Tippett (1937) and others have published successful cases.

This note gives details of my first five cases of fractured patella treated by excision of the fragments, and adds a short commentary on the method. My interest in the fractured patella was inspired in 1930 by my colleague Mr. A J. Couzens, F.R.C S., who had developed an effective technique for wiring and after-treatment. This wiring and postoperative care was satisfactory and patients walked home on the 14th day, but full function of the knee-joint was seldom completely regained. Various troubles were encountered—for instance, sinuses developed and the wire or plaited silk required removal; the fragments separated, or their position after being satisfactory became disturbed; the knee was occasionally stiff, for bony union was always tedious and uncertain and until it was attained vigorous muscular exercise and forcible measures to gain full movement were inadvisable. Flexion was generally limited, a degree of swelling persisted, and pain and fatigue were not uncommon

When Brooke reported his convincing treatment by excision of the fragments, I adopted it, and the results have fulfilled the high expectations The patients are restored to normal although their age in three cases was 72, 60 and 60 The patients were shown at a medical meeting and from their function it was not possible to detect the injured knee.

Case 1: eight months after fracture of right patella.

CASE-RECORDS

CASE 1.—A man aged 72 sustained a fractured patella in a motor accident on Oct 27, 1937. Operation on the 30th. Percaine spinal anæsthesia. A tourniquet was applied. Transverse incision over the gap between the fragments. Fragments found to be widely separated and the quadriceps tendon grossly shredded Fragments excised and quadriceps sutured No difficulty in closing the gap. He was discharged on the 14th day He now has no disability but has experienced a little trouble with varicose veins which were present before operation and have been treated by injection. He had difficulty walking upstairs at first.

CASE 2.—A man aged 60, a window cleaner, fell 22 feet from a ladder, cut his chin, fractured his right tibia and fibula at the ankle-joint and his left patella (compound) on May 14, 1938. Operation later in the day (chin and ankle had already been dealt with) Local infiltration anæsthesia with Pantocaine 1 in 1000 about the patella. Found to have small lacerated wound over the patella and four or five widely separated fragments of the kneecap. Skin wound was excised and extended into a transverse incision Patella was excised and quadriceps tendon sutured with interrupted sutures. Uneventful recovery, almost full function in three weeks This leg is now much better than the other which sustained the Pott's fracture.

CASE 3.—A woman aged 60 fractured her patella without deformity on Oct. 22, 1938. Operation on the 29th under spinal anæsthesia Transverse incision Quadriceps tendon was intact; it was reflected laterally from the fragments and sutured. Patella excised. She was up on the 12th day but had a fainting attack. Went home on the 21st day and now has no disability. Going up and down stairs presented some difficulty for 2 months, but she was unusually apprehensive.

CASE 4.—A woman aged 30 fractured her patella in a motor accident on Nov. 20, 1938. The fragments were not separated. Operation on Dec. 13. Fragments excised and tendon sutured. She walked home on the 14th day and regained stability and mobility almost at once.

CASE 5.—A man aged 35 slipped on the ice and fractured his left patella with wide separation on Dec. 30, 1938. Operation on the 31st under local infiltration with pantocaine. Fragments excised and tendon sutured He returned home on the 14th day and to work on the 30th day.

To summarise these cases, three men and two women aged 72, 60, 60, 30 and 35 have been treated The fragments were widely separated in three and were in apposition in two Interrupted No. 40 thread sutures were used in each and healing was by first intention although one was a compound fracture. Massage and exercises were used in only one case and then as a placebo.

THE OPERATION

The operation is carried out as soon after the accident as the patient's condition permits If possible it is done on the day of the accident This early repair after the injury has been practised since 1930 and no ill effects have followed it The anæsthetics used have been a general once and spinal and local infiltration twice each, the amount of injection necessary to make the latter effective is surprising, a unilateral spinal is probably the ideal

Technique—A tourniquet has been applied occasionally, it is not essential. The incision is a generous transverse one extending well beyond the lateral borders of the patella in order to expose the quadriceps expansion. It is placed midway between the fragments when they are separated or across the centre of the patella if there is no displacement. The hæmatoma in the wound and in the knee-joint is always large and is turned out. The fragments are "filleted" from the shredded quadriceps tendon—a slow and finicky proceeding. The patella is best held with a piece of sterile gauze. The edge of the scalpel is kept cutting on to the bone in order to preserve the tendon as much as possible. The quadriceps expansion is closed by a series of two-hitch interrupted sutures; these do not tend to cut out of the tendon. The thread is tied only when all the stitches are inserted. A little difficulty has been encountered twice *in closing the gap in* the centre, for the tissue has been so fragmented and shredded. Numerous interrupted fine thread sutures (No. 90) were required to "darn" the deficiency soundly with the shreds available. The deep fascia is closed, and then the skin is sewn up with interrupted stitches.

Dressing—A Robert Jones bandage, with at least six alternate layers of wool and bandage is firmly applied, and the limb is loosely tied to a soft head-pillow.

Aftercare—The recovery has been uneventful in all the cases. The pillow is removed on the 5th day, and the patient is encouraged to move the leg in bed and to bend it as much as the dressing allows. *On the 7th day the exercise is increased to sitting up* with the legs over the side of the bed bending and actively swinging them. One layer of bandage and wool is removed per day from now on, *so increasing* the range of flexion, and the use of the limb and foot is diligently pursued. On the 10th day patients get up, put on outdoor shoes (not *slippers*, an important point to avoid a flat foot), and walk with the aid of an assistant and a stick. On the 12th day the stitches are removed and on the 14th day the patients go home. The joint is protected and kept warm by a woollen kneecap, worn day and night. Steadily increasing walks are taken daily and in addition the following exercises are practised, two or three times a day—

(1) Marking time, lifting the knees *high on to the* abdomen.
(2) Swinging the leg back and *attempting* to kick the buttock with the heel while standing, first one and then the other.
(3) Alternate *standing* on the toes and on the heels.
(4) Bending the knees until the patient is sitting on the *heels*.
(5) Kicking the feet forward as high as possible.

No massage is required. These exercises are designed to develop both stability in the limb and mobility in the joint. The *photographs* shown in the figure illustrate how this has been attained, the positions were unrehearsed. The reader is invited to hold this posture while a camera is focused and a snap taken, it will probably be conceded that it constitutes a fair test.

The advisability of *removing* the patella in the absence of separation *will doubtless* be questioned. Its justification is the relief of pain and early return not only to getting about with active unsplinted use of the knee but also to work. Against it is the risk of opening the knee joint, but this factor is to a large extent known and preparations can be made to minimise it.

Incidentally it may be added that good results are reported from excision of the patella in osteo arthritic knees.

SUMMARY

The treatment of fractured patella by excision of the fragments has proved highly satisfactory. The technique is straightforward, patients soon return to work, and full function of the knee is restored.

In five cases, three being over 60, recovery was uneventful.

COMPLETE FREEDOM FROM DENTAL CARIES

A COMPARATIVE STUDY OF TWENTY-FIVE CHILDREN

BY H. G. MILLER, M.B. Durh.

LATE HOUSE PHYSICIAN AT THE ROYAL VICTORIA INFIRMARY, NEWCASTLE-UPON-TYNE

AND

D. M. R. CROMBIE, L.D.S. R.C.S.F.

DENTAL SURGEON TO THE NEWCASTLE-UPON-TYNE EDUCATION COMMITTEE

DENTAL caries is so widespread among human beings that it has come to be considered almost a normal perquisite of civilisation. Even in school children investigations have repeatedly shown an incidence of over 90 per cent., and a really sound set of teeth in an adult is practically unknown. The very universality of the disease makes its ætiology all the more obscure, and the factors which have been implicated at one time or another are many. Briefly, at the moment, medical and physiological investigators are inclined to favour some general cause, in part at any rate a nutritional deficiency, whereas the dentists are more interested in the mechanics of the immediate cause and accordingly lay more emphasis on local factors—dental irregularity, carbohydrate fermentation, changed salivary pH, and defective oral hygiene.

In an endeavour to trace some of the grosser causal factors we made an intensive study of a group of children between the ages of ten and fourteen, with caries-free mouths and no history of caries in the permanent dentition, and compared them with a group showing gross caries but similar in other respects.

We discovered that an investigation on somewhat similar lines had recently been carried out in Leeds by Read and Knowles (1938), who had studied the diet and habits of two groups of 12 similarly selected children. They did not specifically mention inquiry into the family dental history or the personal history of illness, and they did not examine the teeth and inquire into the circumstances of the brothers and sisters of the children in their two groups. On the other hand, they worked out the present dietary of the children in considerable detail. Careful upbringing, *an adequate diet with good protein content and daily* fresh fruit and milk, regularity of meals, limited intake of ferment-able carbohydrate and adequate oral hygiene were among the factors they found to favour freedom from dental caries. They found economic circumstances in the two groups so variable as to be inconclusive, and they observed the relatively low incidence of caries among the inmates of an orphan institution.

PRESENT INVESTIGATION

We classified the severity of dental caries as follows:

	Average number of cavities
A, complete absence of caries	0
B*, very nearly perfect	1
B, slight to moderate caries	2
C, moderate caries	4
D, moderate to bad caries	7
D*, very bad caries	12
E, extreme caries involvement of practically every tooth	20

As a first step, 1842 children, aged ten to fourteen, in Newcastle elementary schools were examined by one of us (D. M R C) and the results tabulated thus:—

A	B*	B	C	D	D*	E	Total
25	88	407	810	451	55	6	1842
(1·3%)	(4·8%)	(22%)	(44%)	(24·4%)	(3%)	(0·3%)	(99·8%)

The 25 children in group A and 25 taken from group D* formed the material for a more detailed study (The latter 25 were selected from the total 55 by taking those attending schools nearest to the place of examination) These 50 children, with their mothers and as many of their brothers and sisters as could be mustered, attended the Raby Street dental clinic of the Newcastle education committee Their mouths were again carefully examined and charted, and a detailed personal and family history of all the children (dental, dietetic, and general) was taken Over 100 children were thus examined, and the mother's health during pregnancy, circumstances of birth, family history, income and housing conditions, infant-feeding, present diet, habits, and past pathological history were investigated in as great detail as possible, the information sometimes being augmented by a visit to the home

RESULTS

A comparison of the social state of the two groups of 25 children gave the following figures:—

	A	D*
Total average weekly income per head of family	10*s* 2*d*	10*s* 6*d*
Average number of live children in family	4·01	4·20
Rooms	3·6	3·1

The chronological distribution of the 25 A and the 25 D* children within their 50 families showed some interesting differences:—

	A	D*
Eldest child in family	15	8
Second child	4	4
Third child	6	5
Fourth or later child	0	8

In other words, A children were often the elder children of the family, whereas the D* children were more often younger children of a family with considerably older brothers and sisters It is difficult not to associate this apparently higher incidence of caries in the younger children of the family with the working-class mother's frequent complaint that *her* teeth were "fairly good until she started having children" Such an association might possibly be related both to maternal calcium exhaustion from the demand of repeated pregnancies and to the unfavourable economic position of the later children in families with relatively fixed incomes

Examination of the teeth of the younger brothers and sisters of the children in the two groups revealed the distinctly familial incidence of dental caries (see table I) (It was possible to examine only these younger sibs mainly attending the same school) Table I shows that 58 per cent of the brothers and sisters of the A children were A, B*, or B, as against 4 per cent. of the D* brothers and sisters, and 96 per cent of the brothers and sisters of the D* children fell into the C, D, or D* class as against 42 per cent. of the A brothers and sisters.

Inquiry into the family dental history elicited the following facts: a strikingly good history on both sides—e g, mother's teeth excellent, grandfather a "sound" head of teeth at 70—was found in 9 A children and 1 D child, and a strikingly bad history on both sides—e g, mother had false teeth at 17, father at 23—was found in 8 D children but no A children The D child with a good history had feeding difficulties and rickets; but in this connexion it is interesting to compare the results of re-examination (by D M R C.) of the 177 children in the Ponteland (Newcastle-upon-Tyne education committee) children's home, not otherwise included in this series but previously the subject of study from other angles by one of us (Miller 1938) which yielded the percentages shown in table II. These figures for the Ponteland children's home compare very favourably with those recorded for any community living under civilised conditions and, together with the fact that most of the caries present was slight or tended towards arrested decay, indicate that any hereditary tendency which may exist is susceptible to improvement in environment even after the age of three years, the age at which children are admitted to the children's home

TABLE I—FAMILIAL INCIDENCE OF DENTAL CARIES

State of teeth	A children's 26 brothers and sisters seen	D* children's 25 brothers and sisters seen	1842 school children
A	1 (4%)	0	1·3%
B*	4 (15%)	0	4·8%
B	10 (39%)	1 (4%)	22·0%
C	5 (19%)	9 (36%)	44·0%
D	5 (19%)	7 (28%)	24·4%
D*	1 (4%)	8 (32%)	3·0%
E	0	0	0·3%

TABLE II—COMPARISON OF INCIDENCE OF DENTAL CARIES

State of teeth	Ponteland children's home		Newcastle schools
	177 children aged 3–18½	115 children aged 9–15	1842 children
A	25·9	27·8	1·3
B*	10·7	12·2	4·8
B	32·2	32·2	22·0
C	21·4	20·0	44·0
D	9·6	7·8	24·4
D*	0	0	3·0
E	0	0	0·3

The inquiry into infant feeding indicates that breast-feeding and perhaps, to some extent, supplementary vitamins appear to be factors in determining later freedom from dental caries.—

	A	D
Breast-fed, wholly or preponderantly until nine months or later	22	15
Artificially fed	3	10
Additional cod-liver oil	11	4
Additional orange juice	14	9

The difference shown by Read and Knowles (1938) to exist between the present diets of their two groups was

so distinct that we hoped to demonstrate such a difference by relatively crude methods of inquiry, but, beyond showing a 50 per cent higher habitual consumption of "fresh" milk (practically all the milk used by both these groups was pasteurised) in the caries free group, our results by such methods were inconclusive Indeed it appears practically impossible to obtain by any method short of direct observation even a moderately accurate qualitative and quantitative dietary history in a human being beyond the age of infancy

In view of the often repeated assertion of a relationship between irregular dentition and caries, the mouths were charted and the following results obtained —

	A	D
Regular dentition	9	9
Very irregular dentition	4	6
Others (not perfectly regular)	12	10

Similarly unconvincing were the findings with regard to oral hygiene 16 of the 25 children with perfect teeth had never used a toothbrush regularly, and 12 not at all

Perhaps the most interesting findings are yielded by inquiry into the histories of past history of common illnesses —

	A	D*		A	D*
Measles	22	20	Pneumonia	2	7
Measles complicated by bronchopneumonia	0	3	Diphtheria	1	0
Pertussis	8	13	Scarlet fever	2	1
			Chronic cough	3	8
			Rickets	0	7

The average age incidence of measles was 4·5 years and of pertussis 5·5 years in group A, and 3·2 and 3·4 years respectively in group D*, and cases of measles in children under 4 years numbered 8 in group A and 14 in group D* The incidence of other past illnesses in the two groups is also very illuminating —

	A	D*		D*
Acute appendicitis	1		"Anæmia"	4
"Tonsils and adenoids	1	4	Chronic abscesses	1
Diabetic (12 months history on 150 g of carbohydrate and insulin)	1		Meningitis	1
			Bronchiectasis †	1
Mastoid		2	Empyema	1
Tuberculous glands		1	Coeliac disease †	1

† Confirmed by hospital investigations

These figures reveal a spectacular amount of past illnesses among the 25 D* "normal" children picked out from their 1842 fellows for examination solely on account of their dental condition Although in some cases the onset of noticeable caries seemed to be directly traceable to some severe illness, no causal relationship can be defined on the basis of this data Nevertheless, reviewing the whole series of cases and the ages at which the illnesses occurred, it is difficult not to conclude that thus high incidence of illness was probably a causal factor in the development of caries Even the maternal health during pregnancy is shown to be different in the two groups —

	A	D*
Toxæmia of pregnancy	1	5
"Unwell" during pregnancy, ranging from anæmia and malnutrition to tuberculosis	0	6

SUMMARY

Examination of two groups of 25 children between the ages of ten and fourteen, one group with complete freedom from dental caries and the other group suffering from gross caries demonstrates certain factors which were apparently associated with freedom from dental caries (1) good family dental history (not apparently of such significance as good general hygiene and diet), (2) careful infant feeding, especially breast feeding, and, probably above all, (3) absence of severe illness and an early incidence of infectious fever No difference of present economic status was demonstrable between the two groups, but a point of importance appeared to be that children with bad teeth were often the younger members of a family, whereas those with good teeth were frequently first children In this series of cases irregular dentition and inadequate oral hygiene did not appear to exercise any unfavourable effect on the degree of freedom from caries

We wish to thank Dr G C M M'Gonigle and Dr J C Spence for helpful criticism and advice, and the Newcastle upon-Tyne education committee for the facilities afforded to us

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTION OF SURGERY

AT a meeting of this section held on July 6, Mr CLAUDE FRANKAU being in the chair, Dr GORDON MURRAY, of Toronto, read a paper on

Heparin in the Prevention of Thrombosis

The properties of heparin as an anticoagulant had, he said been discovered in 1916, he had become interested in it because of the help it afforded in experimental work on blood vessel anastomosis One of the most important steps had been the obtaining of heparin in a pure state whereby its toxicity had been eliminated The *crystalline barium salt* which had been produced had a constant potency Opinions differed as to whether heparin was an antithrombin or an antiprothrombin It might be injected subcutaneously, applied to surfaces, or injected into vessels In vessels its action might be restricted to a length of vessel, or, by injection into the general circulation, it might act by altering the clotting time of the blood This general effect had been found the most useful Veins and arteries could be divided and sutured under the influence of heparin, Dr Murray gave illustrations of perfect healing with complete patency and no evidence of clotting Without the use of heparin, such results were rare, with heparin they occurred in over 90 per cent of cases In grafting experiments—e.g., *of a length of jugular vein into a gap in the carotid* artery—without heparin thrombosis occurred every time within three hours, with previous administration of heparin for 7–9 days by constant intravenous drip—admittedly a difficult procedure to carry out successfully in animals—complete patency of the grafted vessel was assured Dr Murray had followed the histological changes in these grafts up to one year after the operation and was able to demonstrate how the grafted vein gradually assumed the characters of the artery A thrombus produced experimentally by insertion of a foreign body at the bifurcation of a peripheral artery, such as the femoral, could be successfully removed in the heparinised animal

even after it had remained in situ for twenty-four hours and had become attached to the intima Experiments on the splenic vein suggested that heparin had a similar anticoagulant effect in the portal system; in the transplantation of organs also heparinisation ensured success One valve of a heart had been removed and a new valve substituted and the animal continued to live without thrombus formation in the heart

Clinically, heparin had been given by continuous intravenous drip to more than 400 patients without toxic effects; superficial veins near the wrist were used, and no vein had thrombosed up to two weeks. Without heparin it was usual for the veins to thrombose at the end of 26–48 hours. As a preventive of postoperative thrombosis and pulmonary embolism he thought heparin was of value It had been found that the incidence of pulmonary embolism in 600 major operations was 2 per cent , in 400 cases in which patients received intravenous heparin after operation no case of pulmonary embolism occurred Embolectomy was a field of surgery where the use of heparin had been most helpful; 60 per cent. of these operations were successful in heparinised patients The heparin was administered twenty-four hours after the operation, so as to guard against undue bleeding at operation. The clotting-time returned to normal in one and a half hours, and there was no negative phase later on.

In 72 cases of thrombophlebitis in which heparin had been administered the results had been impressive Pain, temperature and œdema had rapidly subsided. The clot was not absorbed In pulmonary embolism Dr Murray claimed no operative success, but in some cases of repeated embolism he believed that heparin had proved of value in preventing further attacks In mesenteric thrombosis, necessitating large bowel resection, success was rare; he had seen only one case recover. But four consecutive cases were alive and well in which the resection had been done and heparin administered. Two subsequent cases died, one after nine days, from peritonitis In splenectomy and in blood-transfusion heparin had proved its value, and there might be a field for its use in coronary thrombosis. The rationale of its use in coronary disease was not clear, but if it were true that occlusion at the commencement was incomplete then heparin might prevent complete occlusion In cases in which heparin had been used all they could say was that the clinical course and the electrocardiograms had been unusual. He described a case in which he had excised a popliteal aneurysm and grafted a length of the jugular vein to re-establish the continuity of the artery The patient subsequently developed an aneurysm in the lower end of the venous graft. This was sutured and the man returned to the Bush with a perfectly normal leg.

Summing up, Dr Gordon Murray said it was proved that heparin was non-toxic, both in animals and human beings; that it prevented thrombosis; that it was valuable in determining success in operations on blood-vessels, and in cases in which thrombosis was a feature.

DISCUSSION

The CHAIRMAN confirmed the value of heparin in the operation of embolectomy. He congratulated Dr. Murray on the brilliance of his work, which he said was well recognised in Toronto

Mr. G. GORDON-TAYLOR said he did not feel so despondent as Dr. Murray about mesenteric thrombosis: almost half his cases had recovered

Sir JAMES WALTON said he knew of no piece of experimental work in surgery which had been so rapidly and successfully carried through or so rapidly applied to clinical use as had Dr. Murray's.

In reply to various speakers, Dr MURRAY said that there was still great difficulty in assessing accurately the heparin content of blood; possibly however in cases with thrombosis the heparin content might not be a significant factor In Toronto they had found it best to determine the individual clotting time for a patient and aim at doubling or trebling that, rather than at producing a standard clotting time. The simplest possible method of estimating clotting-time had proved the most satisfactory, they had given up complicated machines The average case required 750–1000 units of heparin per hour intravenously. The price of heparin was as real a difficulty in Toronto as here; he was afraid it would not be appreciably lower till a synthetic preparation came on the market. There had been successes in septicæmic cases—as, for example, in septicæmia following carbuncles, and physicians were hoping that heparin given in vegetative endocarditis might prevent the thrombus forming on the valve and thus destroy the nidus for the growth of organisms.

OXFORD OPHTHALMOLOGICAL CONGRESS

As is now customary, this congress gathered at Keble College, Oxford, where on July 5 the members met informally and dined in hall The discussions and demonstrations took place at the School of Anatomy, beginning next day with the installation of Mr. PERCIVAL HAY (Sheffield) as master, in succession to Dr C. G. RUSS WOOD, who died shortly after last year's meeting.

Chiasmal Lesions

The Doyne lecture was delivered this year by Mr F. A. WILLIAMSON-NOBLE (London), who took as his subject the Ocular Consequences of Certain Chiasmal Lesions The characteristics of the chiasmal syndrome, he said, include defective central vision, optic atrophy (with or without papillœdema), and very numerous and varied defects of the visual field. The common causes are.—

(a) *Meningiomas* which grow from the dura covering the circle of sinuses surrounding the pituitary diaphragm As they enlarge, these raise the chiasma and stretch both it and the optic nerves. Irregularity of pressure accounts for corresponding asymmetry of the field defects.

(b) *Suprasellar pituitary adenomata* occur either as outgrowths from the stalk of the gland, or from its upper part. In either case there may be a strange absence of signs at first, the most likely evidence being field changes Small test objects and the use of the two-metre screen are valuable in this connexion

(c) *Craniobuccal pouch cysts*, enlarging from remnants of the hypoglossal duct, form a third group They are commonest in childhood, and tend to calcify.

(d) *Arachnoiditis* of the chiasmal region may arise from many causes. The clinical features appear as the result of adhesions or cyst formations. General neurological findings may be absent.

(e) *Aneurysms of the circle of Willis* arise and yield signs after the age of 30 as a rule. Suddenness of onset and pain are the chief features. Radiography may reveal calcification in the aneurysmal wall.

(f) *Chiasmal glioma* is rare. The age-period is youth and there is a tendency towards enlargement of the optic foramina.

Where adhesions develop—e g in syphilitic complications—their division may lead to great improvement of vision by stopping the otherwise inevitable advance of pressure atrophy

Mr Williamson Noble paid tribute to those who, through the media of anatomy, pathology, radiology and perimetry, have helped to provide a reasonable chance of preoperative differentiation, although even now many cases remained unclassified until operation adds certainty to the diagnosis

Vital Staining

Mr ARNOLD SORSBY (*London*), in a demonstration of vital staining, explained that although it has been held that a blood brain barrier resists the vital staining of the brain and its associated element the retina, this is not really correct The reason why the retina does not take stain well is that it has a very high oxygenating capacity If this is impaired by retinal disease, staining will take place according to the degree of the damage In a case diagnosed as retrobulbar neuritis because damage to one optic nerve was seen with the ophthalmoscope vital staining demonstrated damage to the other optic nerve and the condition was traced to a pituitary tumour

Orthoptics

The value of orthoptic training in cases of heterophoria came under heavy cross fire some sang its praises but some thought it an extravagant means of doing what (they maintained) could equally well be done by careful refraction, occlusion of one eye, and attention to physical health

The case for orthoptics was opened by Mr KEITH LYLE (London), while a critique of the method was delivered by Mr F W LAW (London) Much of the argument ranged round the question whether there is any great advantage in educating vision up to the full appreciation of stereoscopic consciousness It is well recognised, as Mr Law pointed out, that many members of the community pass their lives with the comfort of binocular vision but without its higher refinements He granted nevertheless that the arrival of orthoptics has allowed the ophthalmic surgeon to ascertain the exact binocular state of a patient, and that this is a very useful guide for attack upon the squint by surgery It has helped also in the assessment of prognosis The discussion brought out the fact that in heterophoria orthoptic exercises are capable of giving immense relief from headache, strains, and potential neuroses

Other speakers were Miss SHEILA MAYOU (London), Wing Commander P C LIVINGSTON (London), Dr E B ALABASTER (Birmingham), Mr GEORGE BLACK (Leeds), Dr H CAMPBELL ORR (Wolverhampton), Mr P J LLANS (Birmingham) Mr O M DUTHIE (Manchester) and Mr BERNARD CHAVASSE (Liverpool) Miss MARGARET DOBSON (London) showed a film illustrating orthoptic training in cases of convergent concomitant strabismus

The Aqueous Humour

Dr J DOUGLAS ROBERTSON (London) read a paper entitled The Aqueous, a Secretion As a biochemist he has satisfied himself that work is done and energy expended in the formation of the fluid, that a specific substance can be isolated from it, that a chemical equilibrium between blood and aqueous resembles that between blood and a secretion, and that the interchange over the blood aqueous barrier resembles that over the membrane between the blood and the gastric juice, and not that over the capillary intervening between the blood and interstitial fluid

Miners' Nystagmus

Mr T HARRISON BUTLER (Birmingham), in describing miners' nystagmus, laid greatest emphasis upon the toxic and psychasthenic influences at work, and maintained that the miner in general is a highly strung person—partly because of the prevalence of inbreeding in mining communities The toxic influences, he said, emanate from methane, while the neuroses are favoured by the fear of unemployment and by subconscious apprehension of accident It was most exceptional to find a case of miners' nystagmus that could be attributed to deliberate mimicry He doubted whether there is ever a complete recovery in those cases that have endured for some time

Dr DOUGAL CALLANDER (Doncaster) said that when work is good and wages are high the case rate falls sharply away He thought recurrences are rare if the men are given immediate and suitable work above ground

Mr HERBERT CAIGER (Sheffield) spoke of the presence of an inhibitory factor within the cerebral arc, which prevents the onset of acute symptoms even when oscillations are to be seen It is when this natural compensatory mechanism breaks down that the trouble starts On the legal issues, both coal owners and colliers have had grounds for complaint He agreed with Mr Harrison Butler that the perpetual use of the term "miners' nystagmus" is bad, so also is "miners' neurosis"

Sir ARNOLD WILSON, M P, concurred, and said he felt that the cure did not lie with the oculist, but rather within the scope of the physician with expert knowledge of psychology Posture at the coal face has possibly, he thought, been too much neglected

Mr W J W FERGUSON (Sheffield) described experimental studies showing that very bad lighting could be a contributory cause

Protection of the Eyes

Sir ARNOLD WILSON, in a paper on workmen's compensation and disability schedules, spoke of the need to employ protective goggles wherever the eyes are exposed to injury, be it intense light, heat, or flying metal The exhibition of protective shields and tinted glasses on all suitable occasions is important, since it helps the employer of labour to select proper protective materials

Sir ARNOLD LAWSON (London) gave a paper on the application of tinted glasses to industrial and other purposes, and accompanied it by a demonstration of the effects of different coloured filters combined with suitable metal bases (iron or cerium) upon the various components of the spectrum He discussed the influences of these in industry, aviation, and sun glare, and mentioned Crookes, Neophan, and Polaroid He remarked particularly that Protex glass has a strong influence upon the infra red end of the spectrum The problem of glass blowers' cataract is he said, still with us, although glass blowing by hand is now dying out

Miscellaneous Communications

Dr BERNARD SAMUELS (New York) spoke on drusen of the retina H Müller (1858) was first to describe these bodies they are found both in the choroid and optic nerve but only very rarely in the retina He described the histology of the rare type coming from the glial cells of the retina Poor nourishment and irritation are factors in their production

Mr J W TUDOR THOMAS (Cardiff) showed a series of photographs of the results of corneal grafting In one case the donor eye had been enucleated over a

hundred miles from the patient operated upon, and the result was entirely successful Success can be got by using the corneas of cadavers, but actually in one or two attempts of this kind he had not been successful. The cases selected, however, were not promising.

DR LA ROCCA (New York) showed a film of a new method of stitching when operating with corneal grafts.

MR F. E. PRESTON (London) demonstrated a new unobtrusive occluder for raising the vision of amblyopic eyes, and for other cases in which it becomes necessary to occlude. It presents a better appearance than do black shades and entirely opaque glass screens Its value in amblyopia was doubted by some members on the ground that it does not sufficiently eliminate vision.

MR P G DOYNE (London) gave a short communication entitled Number Forms It seems that about one person in thirty sees numbers as patterns of weird shape, curved or angular, with some of the groups accentuated They are set in space as a picture by visual memory They are thought to be caused by such things as the remembered arrangement of clock faces during infancy, and tend to persist in the proportion stated This method of figure visualisation is thought to account for the phenomenon of lightning calculation Those who do not see figures in this way find the process quite beyond their understanding

MR THOMSON HENDERSON (Nottingham) put forward the question, How is a hyphæma or a hypopyon resorbed? He maintained that extensive section-cutting of the eyes of mammals reveals no anatomical barrier at the angle to prevent the free passage of aqueous into the suprachoroidal space He is convinced that this is the normal physiological drainage route of the aqueous

The annual dinner was held on July 6, when there was an attendance of about 130, including Prof. R. R. Macintosh (Oxford) as guest of honour Mr. P. H. Adams (Oxford) acted as deputy master of the congress and Mr F. A Anderson (Shrewsbury) as hon. secretary.

SOCIETY FOR THE STUDY OF INEBRIETY

AT a meeting of this society on July 11 a discussion on

Alcohol and Drug-addiction in Relation to Crime

was opened by Dr NORWOOD EAST, who said that Great Britain had the lowest crime-rate of any great European community and a much lower one than the United States of America, especially as regards violence. In 1937, of 805,336 persons convicted 52,425 (just under 6½ per cent) were guilty of drunkenness, as against an annual average of 193,354 in 1910–14 The number had declined continuously from 1920 to 1932 but had increased each subsequent year In 1937 the number of known drug-addicts was 620, but only 31 persons were dealt with for offences under the Dangerous Drugs Acts, 1920–32, and Regulations thereunder. Apart from drug-addiction, crime might be associated with drug-addiction if a criminal became a drug-addict or if an addict committed a crime, but this was unusual In fact, in this country the relation of drug-addiction to crime was insignificant in comparison with alcoholism.

As regards the incidence of alcoholism in the parents of criminals, in 4000 youths at Wormwood Scrubs prison in 1930–37 a family history of alcoholism was found in 52 per thousand, being more frequent in association with offences against the person, discipline, and property and with multiple convictions; the incidence of a family history of drug-addiction was insignificant (2¼ per thousand) Dr East had investigated the incidence of alcoholism among 100 men and youths tried for murder in post-war years (90 of them in the last ten years) and had found alcohol as a predominant or a contributory cause in 19. He had also examined between April, 1907, and December, 1910, 1000 cases of men and youths charged with attempted suicide and had found alcohol as an important cause in 39 3 per cent He did not know of any statistics showing the relation of alcohol to sexual crimes in this country, but in 1924 he had found only 9 alcoholics among 150 men charged with exhibitionism Criminals sometimes took to alcohol to nullify their inhibitions, and the association of alcoholism with prostitution was sometimes due to the same purpose Every practical criminologist would attach some importance to the association of alcoholism with crime, but it was very easy to over-emphasise the connexion

Insanity might lead to drunkenness, and vice versa. The typical crime committed in mania a potu was one of violence, and the terrifying hallucinations of delirium tremens might be responsible for murder, suicide, violent assaults, or damage to property In the more chronic forms of insanity, theft, fraud, and sexual offences were not uncommon; crimes of violence might be due to hallucinations or to delusions, and crimes of violence, sexual offences, thefts, embezzlement, or vagrancy might be caused by mental deterioration brought on by chronic alcoholism. Criminal conduct was obviously favoured by the abnormal mental condition due to drunkenness apart from insanity. The impairment of reason, the lack of appreciation of the consequences, the emotional disturbance, the divorce from reality, the loss of inhibition, and the consequent unleashing of personal predilections were responsible for many crimes committed by alcoholics

There was a tendency in some alcoholics for subsequent crimes to be of the same pattern as a previous crime, thus resembling some cases of crime due to epilepsy This resemblance might be accentuated if there were no subsequent recollection of the criminal conduct; and, if an epileptic had taken alcohol before committing a crime, the diagnosis between alcoholic and epileptic automatism might be impossible. It was also important to remember that after certain illnesses, such as head injury, brain disease, or a previous attack of mental disease (especially delirium tremens), the offender might be more susceptible to alcohol than formerly—the so-called pathological drunkenness

In considering the legal aspect Dr East said that formerly drunkenness was not accepted as an excuse for crime, because the defendant did wrong in getting drunk, and an offender under the influence of drink could derive no privilege from a madness voluntarily contracted Later it was ruled that, on an indictment for murder, intoxication of the accused might be taken into consideration to show that the act was not premeditated In 1920 the House of Lords decided that insanity, whether produced by drunkenness or otherwise, was a defence to the crime charged

The treatment of the alcoholic and the drug-addict guilty of a major crime was not difficult, for the sentence imposed was usually long enough for the efficient withdrawal of the drink or drug as well as for general and special medical treatment It was more difficult in petty crime associated with alcoholism

or drug addiction because of the shortness of the sentence Compulsory detention of inebriates in the past had been found ineffective in the more advanced cases Medical treatment might be more successful if tribunals had authority to enforce compulsory detention on criminal alcoholics and drug addicts for considerable periods early in their careers Clause 34 of the Criminal Justice Bill now before Parliament proposed to enable courts of assize and quarter sessions to pass two new types of sentence corrective training for not less than two and not more than four years on offenders between 21 and 30 whose records, character, and habits made such a sentence expedient for the training of the offender, and preventive detention for a similar period on persons over 30 whose criminal antecedents and mode of life made such a sentence expedient for the protection of the public Under these provisions some of the more criminal alcoholics would be detained with benefit to themselves and the public Clause 38 enables a medical report on the mental condition to be obtained without remanding the accused, thus inebriety and drug addiction as the underlying cause of the crime might be diagnosed earlier Clause 19 enables offenders with some form of mental illness or abnormality, though not certifiable, to undergo medical treatment as either resident or non resident patients

Too much reliance should not be placed on psychotherapy Evidence was given before the Persistent Offenders Committee in 1931 that psychotherapy had proved successful in only 2 or 3 cases of inebriety out of 60, and in only 1 case out of 11 morphia addicts In an investigation of the psychotherapy of crime at Wormwood Scrubs in 1934–38 no case of alcoholism had been treated by this method, and 4 carefully selected cases of drug addiction gave disappointing results In the report based on this investigation Dr East and Dr W B de B Hubert had recommended the establishment of a special penal institution where psychiatric treatment could be given more effectively than in an ordinary prison to mentally abnormal but not defective or insane prisoners Further investigation, however was necessary before treatment of confirmed alcoholics or drug addicts could be undertaken with confidence

Some women were repeatedly sentenced to short terms of imprisonment for drunkenness and made up the "stage army" of inebriates in the women's prisons Dr J C McI Matheson, governor of Holloway prison, had said that of 2222 women received into that prison in 1936 for various offences 1112 had been convicted of drunkenness, the youngest being 22, 5 per cent under 30, 55 per cent 31–50, and 40 per cent over 50 Dr Hast had been much impressed, when an inspector under the *Inebriates* Act, 1898, by the fact that a considerable proportion of women in the institutions remained in residence indefinitely, although they had not been received under the act and were at liberty to leave They found in the institutions the shelter companionship, sympathy, interest, and freedom from anxiety denied to them in the outer world According to Sir Samuel Hoare the number of habitually inebriate women was steadily and quickly decreasing

In conclusion Dr Hast said that, though the alcoholic, the drug addict, and the criminal were abnormal, the clue to much that arose from their abnormal, the clue to much that arose from their association would be found in the study of normal behaviour Medicine could contribute much to the solution of the problems raised by them, but future social progress and administrative action must be relied on for large scale results

ASSOCIATION OF CLINICAL PATHOLOGISTS

Clinical Pathology of Tuberculosis

At a meeting of this association held in the Coventry Joint Laboratory on July 1, with Dr A F Wright in the chair, a paper on

TESTING MILK FOR TUBERCLE BACILLI

was read by Dr S Roodhouse Gloyne (London) He said that there are three possible methods of carrying out the test—namely, direct film examinations of the centrifuged deposit, cultivation on non glycerinated egg medium, and guineapig inoculation In his experience direct film examination only yields about a tenth of the number of positives that animal inoculation does Cultural methods, though valuable for other fluids and for sputum, are of little use in milk testing, owing to the prevalence of saprophytic aerobic spore bearing organisms The guineapig test not only gives the highest percentage of positives but it is also the only test which can be used as absolute proof in a court of law The drawback of the test is, of course, the length of time taken to obtain the answer He recommends that 100 c.cm of milk should be centrifuged for half an hour at 3000 revolutions per min, and that the centrifuged deposit should be treated for the same length of time with normal soda to destroy secondary organisms and then neutralised with normal hydrochloric acid before inoculation The animal should be killed not less than five weeks afterwards and no case must be reported as positive without definite naked eye signs of tuberculosis (including infection of the regional lymph glands) and the finding of acid fast bacilli microscopically Dr Gloyne's earlier figures—1500 tests for the years 1928–31—showed 9·1 per cent of positives, whilst his latest figures—3960 for the years 1935–39—show only 6·2 per cent Although the two series are for various reasons not strictly comparable it looks as though some improvement in our milk supply is at last taking place A series of 276 pasteurised samples, however, yielded 2·5 per cent of positives, which seems to indicate that not all pasteurisation plants are efficient

COMPARISON OF CULTURE AND ANIMAL TESTS

Dr E N Daley (Gloucester) pointed out that it is in respect of the bacillus most associated with his name that the postulates of Koch are most commonly broken in that as a rule no attempt is made to isolate tubercle bacilli from suspected cases by culture This is because of the difficulty experienced in culturing the organism, but this difficulty has to a great extent been overcome by the introduction of the media of Lowenstein, Petragnani and others Dr Daley's present series of results are based on cultures on Lowenstein medium, but he believes that Petragnani's medium gives greater speed and richness of growth After describing his preparation of the medium and his method of preparing the inoculum by digesting it with 4 per cent sodium hydroxide followed by repeated washings with saline or sterile distilled water, he detailed his results in a series of 112 specimens of sputa, pleural exudates urines, pus and cerebrospinal fluid He had 18 per cent positive on films, 32 per cent on cultures and 29 per cent in animals, when the identical material was used in each instance In another series of 150 cases he had 18·5 per cent positive in films and 37 per cent positive on cultures These specimens were selected

ones from cases where the clinical findings and the direct film findings disagreed In cultures the vast majority showed an excellent growth in three weeks, as compared with five to eight weeks by the animal method In another small series of sputa specially selected as negative on film examination, he found 3 out of 12 were positive on cultural examination. Dr Davey concludes that although the animal will still be the ultimate test of pathogenicity, the cultural method recommends itself as being equally accurate (no positive film failed to produce a growth), quicker and cheaper; it does away with the expense and anxieties of an animal house and the need for procuring a licence for vivisection It is an adequate substitute for the animal test in disclosing tubercle infections in "T.B minus" cases, and would also be a good guide in determining when it is safe to release a patient from isolation in a sanatorium

DIFFERENTIATING SAPROPHYTIC ACID-FAST BACTERIA

Dr H SCHWABACHER (London) recalled the wide distribution of saprophytic acid-fast bacilli in dust and water, and the impossibility of differentiating these organisms from tubercle bacilli purely on microscopical evidence She enumerated the precautions it is necessary to take to avoid the occurrence of saprophytes in films prepared for direct examination.

(a) All containers for pathological material should be cleaned with weak soda solution or bichromate mixture, and rinsed out with hot water and finally with glass-distilled water before being sterilised in the autoclave or hot-air oven

(b) The solutions for the Ziehl-Neelsen stain should be prepared with glass-distilled water. Common baths for staining and decolourising are to be strongly deprecated, for floating organisms are caught on negative slides.

(c) If the slide is not a new one, it should be passed through a bunsen flame 24 times, each to-and-fro passage occupying about one second Only complete charring will remove bacilli once they have been thoroughly fixed on glass

(d) The oil-immersion objective should be wiped in case any acid-fast bacilli have become attached to it from the previous film The oil from the bottle should be allowed to fall on the film, care being taken that the rod does not come in contact with the stained preparation, since otherwise acid-fast organisms may be transferred back to the reservoir

(e) If it is required to rub up material on a slide, a drop of water from a cold water tap should not be used since saprophytes grow abundantly on the mouths of all cold water taps.

The primary colony of tubercle bacilli or acid-fast bacilli usually takes three weeks to become visible on egg medium This primary colony should be sub-cultured on to two tubes of egg medium, the one tube to be used for typing purposes, the other tube, together with a subculture on agar medium, to be cultured at room temperature. If growth occurs at 22° C. the strain is a saprophyte. Tubercle bacilli do not grow at room temperature or on agar medium.

For animal inoculation it is usual to inject 1 mg. suspension of a seven- to fourteen-day-old culture intramuscularly into the left thigh of a guinea-pig and a rabbit. The animals are examined after six weeks and four months respectively. A bovine strain produces progressive disseminated tuberculosis in both animals. A human strain produces progressive tuberculous disease in the guinea-pig, while in the rabbit it only produces a local lesion at the site of inoculation and isolated tubercles in the lungs—i.e., non-progressive lesions A saprophytic acid-fast strain will fail to produce lesions other than a local abscess, however heavy the inoculum

EXCRETION OF TUBERCLE BACILLI IN URINE

Dr. C E DUKES (London) defined urinary tuberculosis as a clinical condition characterised by tuberculous lesions in the urinary tract, by the presence of urinary symptoms, and by the excretion of pus and tubercle bacilli in the urine Tuberculous bacilluria he described as an occult or subclinical tuberculous infection associated with the excretion of tubercle bacilli in the urine but not accompanied by urinary symptoms. These two conditions are both associated with the presence of tubercle bacilli in the urine, but the laboratory findings differ considerably In tuberculous bacilluria only a few tubercle bacilli are found and it is rare for them to be discovered in stained films of the centrifuged deposit. Guinea-pig inoculation is nearly always necessary for the demonstration of tuberculous bacilluria. The excretion of tubercle bacilli is intermittent in bacilluria, so that a test may be positive on one occasion and negative on another The urine looks clear and does not as a rule contain pus or blood, but at the time when the tubercle bacilli are being excreted microscopic examination will reveal an excess of leucocytes in the urine In cases of tuberculous bacilluria the excretion of tubercle bacilli may cease when the patient's general health improves.

In urinary tuberculosis on the other hand the urine usually contains large numbers of tubercle bacilli and they can generally be found in stained films of the centrifuged deposit. Cultures and guinea-pig tests are rarely necessary Dr. Dukes described experiments he has carried out which prove that the excretion of tubercle bacilli is generally constant in urinary tuberculosis. In cases where the bacteria are relatively scarce it is important to examine a concentrated specimen of urine of high specific gravity and containing pus. An early morning specimen of urine is usually best for this purpose. Urinary tuberculosis is almost invariably accompanied by pyuria, and often blood-cells are also present. The excretion of tubercle bacilli continues freely as long as an open tuberculous lesion can discharge into the urinary tract Dr. Dukes illustrated this by photographs of several dissected kidneys showing tuberculous lesions at different stages of development.

GROWTH-RETARDING POWER OF BLOOD-SERUM

Dr. W. PAGEL (Cambridge) said that he has found no growth-retarding power towards the tubercle bacillus in the blood-serum of approximately 90 per cent. of normal persons and those with the "adult type" of pulmonary tuberculosis—i.e., broncho genic phthisis restricted to the lungs. On the other hand, he has observed definite retardation of bacillary growth in about 75 per cent. of cases of "chronic disseminated tuberculosis"—i.e, chronic extrapulmonary tuberculosis, such as lesions of the urogenital organs, bones, joints and meninges He has demonstrated this by a method known as "depth cultures" of tubercle bacilli—namely, mixtures of serum with an asparagin-mineral salt solution and a suspension of tubercle bacilli incubated for 10-30 days He has tested 236 sera in this way. Growth-retardation occurs generally irrespective of the activity of the lesion, although it is more pronounced in active disease, and it is independent of the individual or species resistance to tuberculosis. The serum factor responsible for the retardation of bacillary growth withstands heating for half an hour at 56° C It can be absorbed by a wide range of acid-fast organisms and *Bact coli*, but not by staphylococci and diphtheria bacilli. Absorption is not

stimulated by the introduction of growth promoting factors such as lytic products liberated from the organism used for absorption, nor is it due to an alteration of serum complement It is not unlikely that "natural antibodies" (perhaps similar to the β lysins) are responsible for the phenomenon, because after absorption the bacillary growth is also increased in serum from normal individuals and also because specific vaccination does not confer growth retarding power on the serum

RELATION OF TUBERCULOSIS TO SILICOSIS

Dr A F S SLADDEN (Swansea) gave a statistical summary of pathological examinations of post-mortem lungs from industrial workers supposed to have suffered from silicosis His analysis dealt mainly with a large group of colliery workers, and, for comparison, with a group of other workers subject to silica hazard, but not to coaldust He pointed out that in the first group silicosis was commonly found without any demonstrable tuberculosis, and showed that the relative incidence of tuberculous disease in the second group was double that in the first He referred to other reasons for thinking that a protective factor against tuberculosis exists in coaldust, and put forward the greater frequency of silicosis without superimposed tuberculosis amongst coalminers as an argument in support of this "protective factor"

REVIEWS AND NOTICES OF BOOKS

The Building of a Nation's Health

By Sir GEORGE NEWMAN, G B E , K C.B , M D Edin , F R C P , formerly chief medical officer, Board of Education (1907–35) and the Ministry of Health (1919–35) London Macmillan and Co 1939 Pp 479 21*s*

NOBODY who has the privilege of Sir George Newman's acquaintance will doubt that for him official retirement does not mean an end of intellectual effort Should the storm burst he will play his part, if the clouds pass he, like Allbutt and Osler, will employ his leisure in the service of literature In speaking of his book as a valedictory we certainly do not mean that his public services are concluded But there is a sense in which this book, a history of events in which the author had a large share, may properly be termed a valedictory address and compared with the utterances of predecessors who had served the state in the same field of endeavour Of the three great men whom Newman often names—Chadwick, Farr and Simon—one only composed a valedictory on this scale, and all three retired from the public service with a *sense of grievance* Farr, like Morant, gave his life to the state Chadwick and Simon long survived official retirement but their wrongs sometimes coloured their judgments of men and measures It would be fantastic to suppose that in an official life of nearly thirty years Newman has had no disappointments, never been wounded *and never* wounded others But this book reveals no half healed scars and contains no harsh judgments of individuals

It is, of course, with Simon's books that this book challenges comparison Both writers had a literary *gift* In their official utterances Simon had greater dramatic force, Newman more urbanity Simon was more fitted to startle and terrify, Newman to persuade and please Simon's literary danger was melodramatic violence, Newman's a too easy optimism In this volume Newman's literary merits are conspicuous and the defects of his qualities unobtrusive one can easily understand how far more successful he has been than his great predecessors in interesting the general reader It is of course true that Newman has had a more receptive public than Simon and a sure instinct leads him to emphasise from beginning to end of the book the paramount importance of education, general and technical

Some readers may think that in a comparatively short book too many pages are devoted to the history of education They will be in error Not only a properly educated medical profession but a properly educated electorate are necessary and almost sufficient conditions for sanitary reform In speaking of the decline of infant mortality Newman puts the greatest stress not upon specific sanitary reforms but upon the education of the mothers "Several million mothers became 'child conscious' It was this almost universal *maternal awakening* which really began to change the outlook of child health—as every alert medical officer of health knew in his own district between 1904 and 1910" It is said that Simon de Montfort, watching from Evesham tower the advancing troops and noting their soldierly bearing and formation, said "I taught them that" The youngest and therefore harshest critics of the "optimism" of the Ministry of Health and of the Board of Education in recent years might have railed against but could not have criticised the Ministry without some technical knowledge Newman, directly in his reports and indirectly through the lay journalists who read his reports (a compliment never paid to the writings of Farr and not often paid to those of Simon), has been a great educator

In successive chapters Newman reviews the organisation and training of the medical profession, the development of the Ministry of Health, the awakening of the local authorities These are concerned with matters of general principle and have a logical connexion The next three chapters treat in detail of the problems of school life Then the mother and her infant, the nutrition of the people, the welfare of the industrial worker, health insurance and medical research are studied. The last chapter is a biographical sketch of Robert Morant It may be true that the order of the later chapters of the book is not logical but one has the advantage that each chapter is complete in itself A layman could read almost every word of the book with pleasure and profit and there are very few medical men whose knowledge will not be enlarged by its perusal. As we have already hinted, its literary style is mellower than that of the reports and fully justifies Newman's decision to write a new book and not reprint his papers

No doubt many too young to have personal knowledge of sanitary conditions fifty years ago and even some older people exasperated by the bad side (always so much easier to recognise than the good side) of civil service mentality, will chafe at the easy, urbane flow of the narrative, will find it reminiscent of the eighteenth century It is not that there are no shadows in the picture—Newman has not failed to mention present defects and evils—but undoubtedly the landscape is sunny In this time of A R P distressed areas and general gloom has anyone the right to be bland and optimistic? That is the question one illogically asks oneself But it is quite

irrelevant Newman was not writing a history of modern society but of public-health administration and its relation to the bodily health of our people The story is one of progress Nobody old enough to have had medical experience of (say) East London in the last decade of the nineteenth century will have any doubt on the matter Newman not only had the right, it was his duty to dwell upon the good side of our recent history

In this exhibitionist era valedictories are legion and there is always a welcome for "revelations." It would have been very easy for Sir George Newman to follow many precedents and cast himself for the rôle of the Wise Man hampered by politicians and lay administrators He has chosen a better part and written a book worthy to stand on the shelf next to "English Sanitary Institutions" and sure to be much more frequently consulted

Thorpe's Dictionary of Applied Chemistry

(4th ed.) Vol. II (Bl— Chemical Analysis). By JOCELYN FIELD THORPE, C B E., D.Sc., F.R S., F.I.C., professor of organic chemistry and director of organic laboratories, Imperial College of Science and Technology, London; and M. A. WHITELEY, O B E., D Sc, F.I.C, lately assistant professor of organic chemistry at the college. London: Longmans Green and Co. 1938. Pp. 711. 63s.

THE second volume of this large and valuable work shows little change in policy from that pursued in the first. A large number of experts, representing many branches of science, have contributed a remarkable variety of articles to this volume. Many of them are of special value and interest to workers in the medical sciences, such as those on blood, carbohydrates, cardiac glycosides, carcinogenic hydrocarbons, carotene and carotenoids. We confess to have got most entertainment from the fascinating and informative sections on blacking, brandy, bread, brewing and butter. No less than 170 pages are devoted to a small treatise on chemical analysis which cannot be said quite to fall between two stools, since it describes briefly the methods it recommends, and mostly gives at the same time the appropriate references to original sources This section is well up to date, including most of the new techniques which the analyst has applied to his work in recent times Much of the space in this volume is assigned to pharmaceutical subjects. For a work of reference this makes unusually good reading, it is attractive both in appearance and in substance

Tropical Medicine

(3rd ed.) By Sir LEONARD ROGERS, K C S.I., F.R.C P., F.R S., late medical adviser to the India Office; and Sir JOHN W. D. MEGAW, K.C.I.E., M.B., medical adviser to the India Office. London: J. and A. Churchill. 1939. Pp. 544. 16s

THE authors of this book have both had great experience in the tropics and can therefore tell the student and the medical man what he really needs to know They classify diseases in accordance with their causal agencies, occasionally changing their plan when a clinical classification would be more helpful Thus there are sections on the febrile diseases due to protozoa, spirochætes, viruses, rickettsia bodies, bacteria and helminths, and another grouping the diarrhœal diseases together Snake poisons, dietetic diseases, diseases associated with physical agents, and the incidence of general disease in the tropics all receive notice. The use of the microscope in routine tropical practice, often omitted from clinical textbooks, is here dealt with thoroughly, and rightly so, since the man who tries to practise in the tropics without this instrument is literally and metaphorically working blindly. The revision and proof-reading seem to have been somewhat hurried, for there are a number of minor errors. The book, which is well illustrated with diagrams, photographs and maps, winds up with some general remarks on the diagnosis of fevers and the recording of cases

Klinische Chemie und Mikroskopie

By Dr. LOTHAR HALLMANN, director of the bio chemical and bacteriological department of the Stadtisches Kaiser-Friedrich- und Kaiserin-Friedrich-Kinderkrankenhaus, Berlin Leipzig: Georg Thieme. 1939. Pp. 387. R.M.12.

THIS book deals with clinical chemistry and microscopy in a full and detailed manner, but on blood-analysis it is a little out of date, since many of the techniques described have now been superseded by more recent American methods The book, however, is not likely to appeal much to English readers who are already well supplied with literature in their own language on these subjects

Classic Descriptions of Disease

(2nd ed.) By RALPH H. MAJOR, M.D., professor of medicine, University of Kansas school of medicine. Springfield, Illinois: Charles C. Thomas 1939. Pp 727. 27s.

Prof Major compiled his anthology partly because he is interested in the "actual words" of our predecessors, and partly to enable teachers to bring to the notice of students the first records of much that is now routine knowledge. Those who have the leisure and the taste for gleanings from the past will appreciate the contents but will regret some omissions. Thus Prof Major gives us Thucydides's brilliant account of the plague at Athens, but does not set beside it the equally fine passage in the sixth book of Lucretius on the same theme He gives us Kircher on *contagion*, but not Henle on miasmata and *contagion* But it is churlish at so ample a feast to complain of the absence of particular dainties The good things set before us include Corrigan on Corrigan's pulse; Graves and Basedow on the disease to which either of their names may be attached; Heberden on angina pectoris and on nodes; Nicholas Tulp on diphtheria and on beriberi; and passages from the works of Morgagni, Vieussens, Laennec, Corvisart, Auenbrugger, Schonlein, Caius, Sydenham, among scores of others of greater or lesser note The biographies preceding the excerpts are terse, accurate and scholarly, and sometimes amusing. The brief notice of Nicholas Tulp notes his success in psychotherapy: "he is said to have cured Rembrandt by suggestion of a mental disease which caused the famous painter to believe that his bones were turning into jelly." The paper on Devonshire colic will remind readers of the careful experiments and masterly reasoning by which Sir George Baker discovered that lead poisoning was the cause of this condition. The volume contains much that will be treasured by those interested in medical history. It is perhaps a small thing to set against its merits that though this is a second edition there are many misprints, misspellings and minor errors of printing and punctuation

THE LANCET

LONDON SATURDAY, JULY 15, 1939

THE WATERED MILK BILL

THE Milk Industry Bill presented to the House of Commons in November, 1938, embodied a long-term policy for the production and distribution of milk based on a well known white-paper. This bill was withdrawn in February and the new bill, which was read a second time on Friday of last week, was unfeelingly but aptly compared by a Labour member to the feat of a noble duke who marched his men up a hill and then marched them down again The new bill has avoided controversy by omitting all its important provisions It no longer provides for a milk commission to keep the industry under review and to tender advice when needed, and with this omission disappears also the power to spend money on research and education, gone is the regulation of imported milk and milk products, gone is the power to make pasteurisation orders and to prevent the sale of unpasteurised milk, gone are the schemes to reduce the cost of distribution The first and last of these omitted provisions might have done much to reduce the present high cost of milk to consumers, the third was an overdue step towards making milk safe to be consumed All that is left (excluding minor matters) is extra payment for what is called quality milk, the authorisation of cheap milk for the school population and the extension of the provision for mothers and young children, and the Exchequer grant for milk used in manufacturing butter and cheese

The proposed concessions are in all essentials similar to those in the first bill The payments for quality milk, of which a material part is to be borne by the Exchequer, are still subject to the criticism that "accredited milk," with a bonus of 1½*d* per gallon (½*d* from the Exchequer), is neither safe from conveying tubercle bacilli nor from being a vehicle of other pathogenic organisms It is difficult to see the wisdom of a state contribution towards the production of a quality of milk which, although admittedly cleaner, is little safer than ordinary milk from the risk of conveying disease These proposals are however to operate only from Oct 1, 1938—i e, retrospectively—to Sept 30, 1940 The cheap milk schemes have the same interim character They were welcomed by the medical profession when first introduced and will be again acclaimed, but with the same reservation as regards safety The new bill leaves entirely unsatisfied the unanimous claim of the leaders of the medical profession, which is also the policy of the Ministry of Health, that the milk supply of great Britain should be made safer The milk industry cannot flourish so long as this expert opinion is flouted The only gram of satisfaction is that the present bill is a temporary measure and only postpones for a short spell the realisation of a long-term control of the industry designed both to lower the price of milk and to limit its capacity to convey disease

THE STOMACH IN PERNICIOUS ANÆMIA

Two historical observations In 1870 FENWICK [1] demonstrated structural atrophy and impairment of function in the gastric mucous membranes of patients dying of pernicious anæmia In 1929 CASTLE [2] demonstrated, in patients with pernicious anæmia, the lack of a hæmopoietic substance ("intrinsic factor") normally present in gastric juice Reasonable deduction Fenwick's atrophy is responsible for the deficiency of Castle's factor But that simple putting of two and two together to make four has proved unexpectedly difficult For MEULENGRACHT [3] has shown that in the pig the anti-anæmic factor is to be obtained from the pyloric end of the stomach and the duodenum, but not from the body of the organ, while both he,[4] and MAGNUS and UNGLEY,[5] have recently made it quite clear that the histological abnormalities in the pernicious-anæmia stomach—call them gastritis or atrophy, or both—are conspicuous in the body of the stomach and virtually absent in the pyloric glands and the related duodenal glands of Brunner It is not obvious how structural change in the body of the stomach can explain functional disturbance in normal-looking antrum and duodenum It may be that the pig differs from man, and that the intrinsic factor arises in the former in the pyloric region, in the latter in the body The anatomical similarity between the two species, however, makes this unlikely, and MEULENGRACHT prefers to suggest other reconciliatory hypotheses that the pyloric and Brunner glands, like the islets of Langerhans, can fail in function while structurally intact, that they require activation by a hormonal product of the mucosa of the body of the stomach, much as the pancreas requires secretin, or even that the main disturbance in ordinary pernicious anæmia is more a failure of intestinal absorption of the anti-anæmic product than a failure of production of one of its factors

Hitherto the gastric atrophy has usually been looked on as extensive and irreversible This has perhaps been too readily inferred from the well-established fact that the gastric mucosa in treated cases practically never recovers the power of secreting acid The proof of the matter lies with the pathologists, but their opportunities of examining well fixed stomachs of pernicious anæmia patients dying in remission have not yet been numerous Meanwhile the gastroscopists have entered the field, and the claim of JONES, BENEDICT and HAMPTON [6] to have demonstrated regeneration

of atrophic gastric mucosa in treated patients has been followed by a more extensive study from SCHINDLER, who is one of the parents of the modern gastroscope. It concerns 23 patients with well-attested pernicious anæmia. In most of those who were untreated SCHINDLER and SERBY [7] saw the well-known and easily recognised atrophic features—thinness and greying of the mucosa and visible fine red branching vessels In some the atrophy was extensive, in others only patchy and discrete; it usually affected the body of the stomach, but in one case was most marked in the antrum, and in another case SCHINDLER satisfied himself that no atrophy, only a superficial gastritis, was present. Many of the patients were re-examined after some months of liver treatment, when their blood-pictures had returned to normal. Four of them showed little change; in one the atrophy had advanced, in four or five the gastric mucosa presented a normal appearance If this be accepted it will reconcile the discrepancy between the claim of JONES, BENEDICT and HAMPTON, and the failure of HARTFALL [8] to find any convincing gastroscopic evidence of regeneration during remission under treatment. Both seem to be right, and the stomach may sometimes (but not always) behave like the smooth glossy tongue, which recovers its pile when liver is given. But this does not simplify the pathogenesis of pernicious anæmia It forces SCHINDLER and SERBY to the assumption that in this condition two separate disorders of the stomach are present: first a dysfunction of the cells producing Castle's intrinsic factor, and secondly a degenerative and inflammatory change in the gastric mucosa which, sometimes at least, recovers under liver treatment and therefore may be attributable to a deficiency state. To these may be added a third disturbance, the achlorhydria, which accompanies the first. SCHINDLER and SERBY do not consider the alternative possibility that the atrophy of both tongue and stomach may be due to the prolonged anæmia itself, for both may be found in the common hypochromic anæmia due to iron deficiency; the gastric atrophy—as judged by the gastroscope—might be reversible in the less advanced and irreversible in the more advanced cases. That view has at least the merit of simplicity, and should be refuted before a new specific deficiency is invoked

THE HOLIDAY

THE decision how we shall spend our holidays often represents a compromise in which our individual choice may have played only a minor part. Custom, the claims of children, international tension, familiar problems of time and money—there are many constraining influences upon personal wishes. But it is doubtful what our personal wishes and wants are. Many of us, about to go on holiday and having nothing to consider but our more selfish desires, can hardly be sure what it is that we want of the holiday. Is it to be idleness or activity, or perhaps an alternation of each? Shall our activity be as different in kind as it can be from our daily work? If we are people who work with our heads all the year round, shall we now pile up the lactic acid and the stiffness by physical exertion and let the cortex rust? Shall we ride a hobby or a horse, cultivate our æsthetic leanings or our gardens? Not all who make their choice in these matters are confident beforehand, or afterwards, that this is the ideal holiday they have chosen "Change of scene" is an old prescription and "rest" is an older one—as old as the sabbath. But change of scene is nowadays interpreted as a psychological, not a geographical and climatic affair, and rest is a qualified notion, implying rest (i.e. change) from one's usual activities rather than the utter rest of quasi-stupor.

It might be expected that the psychologists and psychiatrists would have something to say about all this; the psychology of industry has had much occasion to study the need of rest and the forms rest should take, and the psychiatrist is continually dealing with jaded people. Ordering people away for the sake of their nerves has been a well-known function of the physician. But it is decidedly unusual in our days for the psychiatrist to advise a sea-voyage—or travel of any kind—as a remedy for the surfeit and weariness of neurotic depression. He may, it is true, occasionally think that the sympathetic stimulation of mal-de-mer will have the salutary effects attributed to it in the treatment of schizophrenia by sages of the past (and the present), but in general it is not change of scene as an end in itself that is of value in his eyes but rather change of milieu (such as might even be attained while one stayed at home) whereby one escapes from emotional bonds and complexities, from harmful associations, reminders, habits. The psychiatrist is not concerned to get the patient away from himself but rather to create the conditions in which he may return to himself, give freedom and expression to inhibited or thwarted inclinations the standpoint is more that of Rousseau than of the Scarlet Pimpernel. When the psychiatrist advises his patient to enter a nursing-home or clinic it is not for Weir Mitchell treatment—that negation of activity, that winter holiday of the dormouse—but for a regimen in which every hour is planned and occupation more conspicuous than recreation Often the psychiatrist sees that it is the very breadth of choice open to the irresolute patient that has been beguiling and bothering him; his days must be arranged for him, occupation imposed upon him, sometimes with no more cooperation on his part than he gives to his dietary or medicinal regime Sometimes the occupation proposed will be close to the patient's work in ordinary life, so that he is not called on for the effort of acquiring a new skill, sometimes it will be remote and will demand effort and patience both from him and his teacher-therapist. The psychiatrist has not yet worked out the principles on which his occupational therapy rests and by conscious application of which he can prescribe it; it is useless to appeal

[7] Schindler, R., and Serby, A. M., *Arch. intern. Med.* 1939, 63, 331

[8] Hartfall, S. J., *Proc. R. Soc. Med.* 1939, 32, 527

to him to tell us how far they are applicable to the holidays, salutary or therapeutic or prophylactic in intention, which healthy people take The same is true of "recreational therapy," now increasingly employed in the treatment of the mentally ill, but still without precision At all events such things as private worries and desires, occupational and social troubles, temperament, opportunity and training make any simple or general rule impossible, whether it be for the treatment of the sick by clinic holidays or for the healthy man walking into Cook's to book his berth

The physical advantages of a holiday are obvious but do not always run parallel with the psychological ones In the latter it is freedom from insistent anxieties and restraints that works most efficiently Contentment in what one is doing on the holiday, whether it be yachting or learning Chinese, release from irksome conventions and ties, freedom to follow one's bent (towards dirt or dilatoriness, floating or diving)—these will be more potent than change of air Indeed, if vocational guidance, mental hygiene and our social system had all attained perfection, we should find in our daily working lives, as a few lucky dogs do, such satisfaction and freedom that holidays would be superfluous There will be no holidays in heaven

ANNOTATIONS

THE PROCESS OF AGEING

WITH the steady increase in the average age of the population the physiology of age becomes more and more important, yet its study is still largely neglected The healthy young adult can no longer claim to be typical of the human race, but must give place to the man of 35 The great problem in nearly every aspect of ageing is to differentiate pathological processes from those due to time alone, the longer an organ or tissue lives, the more likely is it to suffer from trauma or infection A remarkable study [1] of the biological and medical aspects of ageing made by Professor Cowdry of Washington University, St Louis, and others, deals not only with every part of the body but with the mind as well The early chapters on plants protozoa and insects show how fundamental are the problems to be tackled In some of the chapters "ageing" is interpreted as meaning any change taking place with time, the twenty six authors having insufficient material on which to base conclusions about advanced age Occasionally indeed the object of the book seems to have been forgotten for a paragraph or two, but this is in keeping with one of the two strong impressions gained by the reader The first of these is that here we have an anatomical physiological study of the body by a number of persons of many and diverse interests, and, quite apart from the object of the work, the result is an extraordinarily interesting collection of facts presented in quite a new way It would be difficult, for instance, to find in any ordinary textbook such an informative chapter as that on lymphatic tissue, yet the facts given are not of such a type as one would expect to have to search for in special places The book might with advantage be combed by teachers of anatomy and physiology for points which they have overlooked or about which they thought nothing was known The second impression is one of surprise that so much research has been done on the question of age from one aspect and another, and that so much knowledge has already accumulated—much of it of direct interest to the doctor who too often feels that in the treatment of elderly patients he has to lean too heavily on his personal experience and certain vague traditional ideas The book has been deliberately produced in order to foster scientific interest in the subject of normal ageing and one of its objects is to demonstrate the large gaps which still exist The study is timely from the scientific point of view in that a suitable moment has been chosen for a stocktaking of existing knowledge, and from the sociological point of view in that everyone is now "population conscious"

COLOSTRUM AND IMMUNITY

ALMOST every textbook of obstetrics and pædiatrics mentions vaguely that one of the functions of colostrum is to convey immunity to the newborn baby, but scientific evidence of this important fact, if indeed it is a fact, is scanty, and experimental work in the veterinary world is not necessarily applicable because anatomical differences in the formation of the placenta in different species introduce the difficulty of distinguishing between immunity transferred through the placenta and through the colostrum Schneider and Szathmary [1] have now studied the antibodies in the colostrum of cows and in the blood of newborn calves By inoculations they raised the immunity of pregnant cows to 170 diphtheria antitoxin units per c cm of blood and an antityphoid titre of 1 in 100 At this stage colostrum was withdrawn and found to contain 1400 units of antitoxin and an antityphoid titre of 1 in 5000 Roughly speaking then at this stage of pregnancy 1 c cm of colostrum is equivalent to 10–50 c cm of maternal blood serum as regards its antibody content Immediately after birth and before being allowed a feed calves from these immunised cows were found to have less than 0 02 unit of antitoxin per c cm of blood serum and no trace of typhoid agglutinins Within ninety minutes of the first feed of colostrum however, the antitoxin content of the calves' serum had risen to 0 25 unit per c cm and an agglutinin titre of 1 in 1 After twenty four hours of normal feeding the antibody content of the calves' blood was about 10 per cent of that of the maternal serum By this time ordinary milk was being secreted, which only contained negligible amounts of antibodies as compared with colostrum

These results confirm the eminently practical effects obtained in the prevention of lamb dysentery whereby the ewe is inoculated with a vaccine and immunity is conferred on the lamb provided that an early colostrum feed is allowed How far these results could be applied to human medicine cannot be estimated for lack of data Clearly the primitive nature of the bovine placenta prevents any transplacental interchange of serum proteins, whereas this

[1] Schneider I and Szathmary, J Z Immunitätsforsch 1938 94 454

is not true of the human placenta. The matter is capable of relatively easy determination, for example, by estimating the diphtheria antitoxin content of maternal serum, colostrum, and the serum of the newborn human baby The mechanism whereby the bovine lactating tissue mobilises, concentrates or synthesises antibodies for excretion in the colostrum also demands careful study Finally, the absorption of immunising substances from the gastro-intestinal tract in the calf and lamb opens up another field of experiment in the human subject, in whom it has become routine practice to give immunising agents parenterally The question "does colostrum really matter?' is one which pædiatricians would like answered.

THE FRONTAL LOBES

OPINION regarding the importance of the frontal lobes for the life of the mind has fluctuated during recent years The recognition that tumours involving the frontal lobes are apt to produce severe mental changes led to the belief that this part of the brain was concerned in some special way with mental function Later it was appreciated that such changes were probably in part remote effects of the tumour The increasingly radical measures of neurosurgery have provided the opportunity of observing the effects of unilateral and even of bilateral frontal lobectomy in man and of comparing the human reaction to such cerebral amputation with that of experimental animals Recent writers, notably Penfield and Jefferson, who have studied the results of unilateral frontal lobectomy have tended to stress the slightness of the consequent mental symptoms, and Jefferson has argued that the frontal lobe has no functions for the mental life that are qualitatively different from those of any other part of the brain.

Dr. Gösta Rylander[1] of Denmark has studied the effects of unilateral frontal lobectomy in 32 cases. His psychiatric outlook has enabled him not only to make an exceptionally thorough psychological investigation of his patients but also to assess the shortcomings of individual tests He lays stress on the importance of the patient's preoperation personality and carefully avoids dogmatism, pointing out that symptoms are often capable of more than one psychological interpretation. His investigation shows that skilled psychiatric examination reveals a fairly constant change both in the intellectual and emotional spheres in patients in whom one frontal lobe has been removed The emotional changes consist of a diminished inhibition of affective responses and a displacement of the habitual feeling level, in most cases towards euphoria In the volitional sphere restlessness and deterioration of initiative and interest are characteristic The intellectual changes involve mainly the higher faculties

TREATMENT OF SERUM SICKNESS

BOTH the incidence and severity of serum reactions have diminished sharply since the introduction of concentrated therapeutic sera The common type of reaction encountererd nowadays consists of a generalised urticarial rash with or without constitutional disturbance—an event which may prove extremely irritating to the patient but does not endanger life When the need for antitoxin is urgent, as in diphtheria, the possibility of reaction must not be allowed to interfere with specific treatment In non-lethal diseases, however, such as mild, or even moderate, scarlet fever there is a natural inclination to weigh the advantages of serum therapy against the chances of serum sickness—from the patient's point of view the cure may seem worse than the disease

None of the remedies so far advocated for the control of serum sickness have proved more effective than the subcutaneous injection of adrenaline chloride in combination, if necessary, with ephedrine by mouth Foshay and Hagebusch,[1] working on the hypothesis that the major phenomena of serum sickness are due to histamine or a histamine-like substance, have sought to control it by administering an inactivating ferment obtained from the intestinal mucous membrane (histaminase). This compound, in the form of enteric-coated tablets, was given to a preliminary series of 8 cases of serum sickness, but the results were rather inconclusive, presumably because of irregularities in absorption Accordingly a further 13 cases were treated with an injectable form of histaminase either alone or in combination with tablets by mouth These patients, suffering variously from the effects of horse serum (8 cases), antitetanus serum (4 cases) and scarlatinal antitoxin (1 case), were all relieved to a considerable extent, but in more than half of them the benefit was not apparent for at least eighteen hours—long enough to introduce the possibility of natural recovery In an attempt to determine the prophylactic value of histaminase 8 patients were treated on the day before and for a certain time after the administration of different types of antitoxic sera Only 2 patients developed serum reactions, and these were very mild, which suggests that histaminase did have some preventive effect, though to be at all conclusive a longer series would be necessary. Meanwhile reactions may become negligible through the wider use of more recent methods of serum concentration and refinement Bradshaw's[2] incidence of 1·2 per cent of reactions in a series of 793 injections of refined (predigested) scarlatinal antitoxin certainly encourages this hope

A PIONEER IN BIOCHEMISTRY

FIFTY years ago died one of the first scientists to draw attention to the chemistry of urine—George Owen Rees, scion of a Welsh family whose ability has won them several niches in the "Dictionary of National Biography" Thus, his great-grandfather was Owen Rees, a nonconformist minister; his grandfather was Josiah Rees, a Welsh presbyterian minister, an uncle, Owen Rees, migrated to London and became a partner in the publishing firm of Longmans; and another uncle, Thomas Rees, at first in trade as a bookseller, later became a unitarian minister and a voluminous writer on theological and historical subjects A third of these brothers, Josiah Rees, was a Levantine merchant and was appointed British consul at Smyrna; he married an Italian woman, by whom he was the father of George Owen, another son, and a daughter

George Owen Rees was born in 1813 and was apprenticed at Guy's Hospital in 1829 In 1836 he studied botany under Sir William Hooker, took his M D Glasg, and returned to start practice in London An account of his activities is given in *Guy's Hospital Reports* for January. His ability attracted the attention of Bright, Swayne Taylor, Roget

1 Personality Changes after Operations on the Frontal Lobes By Gösta Rylander London Humphrey Milford, Oxford University Press 1939 Pp 327 15s

2 Bradshaw, D B, *Lancet*, July 1, 1939, p 6

(secretary of the Royal Society and author of the famous "Thesaurus"), and Brodie, on whose recommendation he was appointed medical officer of Pentonville. In 1836 he published "On the Analysis of the Blood and Urine in Health and Disease," one of the earliest works on biochemistry. In 1838 he demonstrated hyperglycæmia in diabetes, being the first to make a quantitative estimate of blood sugar. Results of his team work with Bright on Bright's disease were published in *Guy's Hospital Reports* in 1843, with an appendix by Rees on "Observations on the Blood with reference to its peculiar condition in morbus Brightii." He had previously helped Bright in his work on jaundice. For many years he assisted Swayne Taylor in his toxicological work, giving evidence in the Palmer and other celebrated trials. Rees gave the Goulstonian lectures in 1845, the first Lettsomian lecture at the Medical Society of London in 1850, the Croonian lectures in 1856, and the Harveian oration in 1869, in which he suggested that "nerve force" might be analysed with the help of chemistry (see *Lancet*, 1869, 2, 26).

George Owen Rees died of cerebral hæmorrhage on May 27, 1889. He never married, having devoted his life to science and to the support of his impoverished mother, brother, and sister.

THE ALMONER AT THE V.D. CLINIC

THE post of lady almoner to a clinic for venereal diseases is one that calls for exceptional gifts. The patients who attend such a department are in general far from being the moral outcasts and degenerates that the public, and only too many of the medical profession, believe them to be. Usually they are ordinary human beings in serious trouble who are abnormally resentful of prying interference but highly responsive to sympathetic understanding. The almoner's work, therefore, has many pitfalls and many discouragements, but also many compensations to one endowed with a proper understanding and trained in the right methods of approach. Miss Manchée writes[1] from considerable experience at St Mary's Hospital, and her book is full of useful information for those who would tread this thorny path. The introductory chapter by the medical director of the clinic at St Mary's gives a concise summary of the main facts about the venereal diseases and their treatment which the almoner should know—knowledge which is essential in her work but is ordinarily hard to acquire. Succeeding chapters deal with the general duties of an almoner, and the work of record keeping, and contain much tabulated information about treatment centres, special hospitals and organisations. Others are devoted to the particular problems of following up, of maternity patients and of infected children. Miss Manchée's personal views are sound and instructive, but may be open to criticism on points of detail.

She rightly emphasises that the first interview is the most important, but it may be argued that the patients need not be questioned as to both medical and social circumstances *before* seeing the medical officer. Many would resent such cross-questioning, although they would be willing to give particulars to the medical officer or later to the nurse who is giving treatment, after which, if help is needed, they could be referred to the almoner. Then is the difficult question whether a visit should be the final step in following up when letters remain unanswered. As Miss Manchée says, "untold harm can be done through thoughtlessness or over-zealousness" and many would regard such visits as a serious manifestation of excessive zeal, except perhaps in the occasional case where a child's health is being jeopardised by parental carelessness or ignorance. In all these situations wise restraint is the first essential, and the almoner who is over active will do more harm than good. To those who possess the necessary qualities and would attempt this difficult task, the present book is likely to be a substantial help.

A FRIEND OF CHILDHOOD

Miss Clara Andrew, who died last week, had an idea in 1914 and spent the remaining 25 years of her life in working it out. The idea was to give childless couples the opportunity of bringing up children who had no proper homes of their own. It started with her Belgian refugee work but soon broadened in the atmosphere of war-time generosity. She had little difficulty in finding permanent homes for war orphans and then set about protecting not only the adopted children but also the adoptive parents from later interference. The act of 1926 giving both parties legal status is now a common place, it was actually the result of long and patient labour, and Clara Andrew was not content to leave it there. She helped to obtain the appointment of a departmental committee to consider further safe guards and its recommendations are now awaiting royal assent. It has been said that she found homes for more than 6000 children, of whom no more than 30 proved misfits. This was in itself no mean achievement, but she did more than this, for she and her co workers have almost redeemed the phrase "baby farmer" from its terrible associations.

ERRORS IN THE DIFFERENTIAL BLOOD COUNT

MANY American hæmatologists have claimed that more accurate differential cell counts are obtained when the smears are made upon cover slips than when they are prepared on slides. Boveri[1] has accordingly undertaken some comparative studies of white cells by the two methods. These comprised differential counts on himself on twenty six days at approximately the same hour of the day. Two films were made on slides, four films (two pairs of films) on cover slips. On each of the two slide films 600 cells were counted, making 1200 in all, and on each of the four cover slips 400 cells, making 1600. At the same time as a check the lymphocytes were counted in a Buerker chamber against the remaining types of cells taken together. It was thought that the percentage of lymphocytes obtained in this way would represent fairly accurately their percentage in the original drop of blood. The lymphocyte counts obtained from the cover glass counts and the Buerker chamber counts agreed closely, the average difference being only 0·5 per cent. The lymphocyte percentages obtained from the slides were constant and higher by approximately 10 per cent. In other words the lymphocyte percentage ranged between 20 and 30 by the counting-chamber and cover slip technique and between 30 and 40 with the slide method. There was little to choose between the two methods as far as consistency. For the slides the average difference was 2·15 per cent and for the cover glasses 2·2 per cent. The high lymphocyte count is due, Boveri believes, to the tendency of granulocytes and monocytes to congregate near the

1 Social Service in the Clinic for Venereal Diseases. By Dorothy Manchée. London: Bailliere, Tindall and Cox. 1938. Pp. 91. 3s.

1 Boveri, R. M. *Guy's Hosp. Rep.* 1938, 88, 112.

edges and ends of the film He thinks it difficult to compensate for this by counting in a standard way that includes representative portions of the film He concludes that the cover-glass method is the best, for it alone gives a differential count that correctly represents the relative proportions of the different types of white blood-cells in the original drop of blood. It is not, however, easy to carry out, and is therefore unsuitable for anyone but a highly trained worker He suggests that in hospitals, where blood examinations must often be made by the inexpert, it is wiser to sacrifice precision to uniformity The slide method should, he thinks, be used for routine purposes, remembering that the normal lymphocyte percentage then ranges between 25 and 40.

TISSUE RESPIRATION

AT the Dundee meeting of the British Association, to be held from Aug 30 to Sept 6, the sections of chemistry and physiology will jointly discuss tissue respiration The opener, Prof R A Peters, F R S, will be followed by Malcolm Dixon (Cambridge) and H Theorell (Stockholm) speaking respectively on catalysis and the flavoproteins After an account of cytochrome and similar compounds by Prof David Keilin, F R S, F Dickens (Newcastle-on-Tyne) will consider the interpretation of intermediary metabolism from measurement of tissue respiration, and J H. Quastel (Cardiff) that of narcosis. S Ochoa (Cambridge) will deal with carbon-dioxide evolution and cocarboxylase Prof H S Raper, F.R.S, will discuss the control of tissue respiration, and other aspects of the subject will be presented by D. E Green (Cambridge), Sir Gowland Hopkins, F.R S, H A. Krebs (Sheffield), T. Mann, and E P Poulton (Guy's Hospital)

OPIUM AND CODEINE

ATTENTION has from time to time been called in these columns to the use of codeine as a drug of addiction and the question of extending to it and its salts certain provisions of the 1931 convention for limiting the manufacture and regulating traffic in the drug. The matter has again been under the consideration of the council of the League of Nations and of its advisory committee on opium traffic Codeine was included in the first draft of the Hague Opium Convention of 1912 but was finally omitted under pressure from the German delegates Representations from Canada that codeine appeared to be replacing morphine among drug-addicts and restrictions placed upon its use in certain countries, such as Poland and Switzerland, led the advisory committee of the League to draft a protocol for bringing dihydrocodeine and its salts under control like other dangerous alkaloids This draft has been communicated by the Secretary-General to governments, and their observations have led to the preparation of a revised draft which the council of the League has recently approved for consideration by a conference about to be summoned

The advisory committee was in session during May and June when Major W. H Coles (United Kingdom) was elected chairman and Sir Thomas Russell, Pasha (Egypt), vice-chairman The other nations represented were Belgium, Bulgaria, Canada, China, France, Greece, Hungary, India, Iran, Mexico, Netherlands, Poland, Portugal, Siam, Switzerland, Turkey, United States and Yugoslavia. Sir Malcolm Delevingne and M. A L Blanco (Spain) also attended, the former in the capacity of an expert and the latter as an observer. Besides the usual progress report and the returns of illicit traffic and seizures the committee further considered the alarming situation in the Far East and the fundamental question of the limitation of cultivation of the opium poppy and of the production of raw opium.

BLOOD-DONORS COMING IN SLOWLY

DURING the first three days of the appeal for volunteer blood-donors some 5000 people registered as willing to contribute blood in the event of a national emergency. This has been regarded as a good or a bad beginning according to the commentator's forecast of future progress. Certainly the start has been unnecessarily slow, but later figures show a quickening response If war broke out at least 100,000 donors would be required in London alone and the empanelling centres are in a position to test and register at least 30,000 volunteers a day It does not need a prophet to be sure that if an emergency arose blood-donors in sufficient number would at once be forthcoming, but an adequate supply of blood of the proper groupings could not be made immediately available It might be well for practitioners all over the country to impress their patients and others with the fact that now is the time to do it—in the words of the prescription, *tuto cito jucunde* There may be an understandable reluctance to face a situation that may not and should not arise, but at least there need be none of the present hesitation as regards risk to the volunteer Long experience has shown that occasional giving of blood is harmless to donors, and all that is asked of them in peace time is the surrender of two or three drops for testing It is here that the family doctor's assurance would count for much The list of blood-transfusion and empanelling centres which has now been issued shows the very large number of places at which the volunteer can register any day in the week except Sunday, from 10 to 12 and from 5 to 8 o'clock. In London itself there are 51 such centres; in the home counties, 36; in provincial centres, 41 (with, in Liverpool, all the Ministry of Labour offices); in Scotland, 12; and in Wales, 4 In London the address of the nearest empanelling centre can be obtained at any post office, or by telephoning Central 8691.

BORNHOLM DISEASE

THE disease variously known as Bornholm disease, epidemic pleurodynia and acute epidemic myalgia is a comparative newcomer to the medical world. References to it are found as early as 1856, but it was first systematically described in 1930, when an epidemic was reported from the Danish island of Bornholm. Since then there have been outbreaks in various countries and the clinical picture is now firmly outlined, though the ætiology remains unknown Weterings,[1] who reports three cases from Holland, points out the similarity between Bornholm disease and abortive acute anterior poliomyelitis Bacterial examination of the blood, cerebrospinal fluid, fæces, and smears from the nose and pharynx have been negative in every case so far reported, and the probability seems to be that a virus is responsible. The cardinal features of the disease are as follows. It mainly affects children and young adults between 4 and 20 years, though it has been described in older people, most cases arise during the summer, and usually in epidemic form; the illness starts abruptly with severe pain, situated as a rule in the lower part of the chest and upper part of the abdomen on both

1 Weterings, P A A, *Ned Tijdschr Geneesk.* 1939, 83, 2326.

sides, but sometimes in the back or lower abdomen, and accompanied by rise of temperature to between 100° and 102° F, recovery from the initial attack takes place after about 24 hours, but there is usually a relapse on the third day, again lasting about 24 hours, and pathological examination is negative

The prognosis is wholly favourable, and the chief importance of the disease lies in the readiness with which it may be mistaken for more serious conditions—for example, acute appendicitis, perforated peptic ulcer, pneumonia or pleurisy Of Weterings's three patients one was admitted to hospital as a case of acute appendicitis, one as perforated peptic ulcer and one as diaphragmatic pleurisy All three seemed seriously ill on admission, and the first two showed pronounced muscular rigidity The first patient, a youth of fifteen, was operated on for supposed perforation of a peptic ulcer, and only the fact that the symptoms were very similar saved the second patient from an unnecessary operation Bornholm disease is uncommon but it should be thought of in the differential diagnosis of an acute abdomen

NATIONAL CAMPS

THE Minister of Health has told the House of Commons of the progress so far made in implementing the Camps Act The National Camps Corporation Ltd has inspected 155 sites of which 30 have been approved for use as school camps in time of peace and as evacuation camps in time of war, of these sites two have been given to the corporation and the others have been purchased or are shortly to be purchased The camps are being built to the design of the consulting architects, Sir John Burnet, Tait and Lorne, the buildings will be of Canadian cedar with cedar shingle roofs Each camp will be laid out by an architect selected from a panel approved by the Royal Institute of British Architects Work has begun on two camps in the county of Oxford, one in Hants and one in Bucks, and seven others will be started within a few days The first camp will be completed by the end of August

CHEMOTHERAPY AND THE WHITE CELLS

Dr Leonard Colebrook's letter on p 158 should be read by all who use sulphanilamide, and they are many It is more than three years since we published his first report, with Dr Mervc Kenny, on the effects of Prontosil in puerperal sepsis, and as a pioneer of the new chemotherapy his plea for caution demands respect from more recent adherents He is concerned, as will be seen, with the risk of inducing with sulphanilamide and its congeners a dangerous or even fatal diminution of polymorpho nuclear leucocytes At a time when tons of these drugs are being consumed in Europe and America every month, if not every week, it may seem that this risk is remote, since very few fatal cases have been reported But the question arises, Are they recognised? Are not the toxic symptoms usually put down to the illness for which the remedy is prescribed? Elsewhere in this issue Dr French records a study of the blood of children given large doses of sulphanilamide over longish periods, and like Britton and Hawkins, who gave smaller quantities to ambulant patients she notes a slight but constant depression of polymorphs, which might well become serious where the bone marrow was already depressed by infection The bright side of chemotherapy is represented by the paper on p 148 by Prof Baird and his colleagues at Aberdeen, where prontosil was introduced in 1936 Their few fatal cases, however, include one, hitherto unrecorded, in which high dosage (in 1937) produced agranulocytosis, and we fear that in private practice this disaster is still not uncommon though often misinterpreted Dr Colebrook makes practical suggestions for its avoidance, while on another page Prof Campbell and Dr Morgan write encouragingly of the prevention of another and less serious complication—methæmo globinæmia—by means of methylene blue

DANZIG SCHEME FOR EARLY DETECTION OF CANCER

ON June 1 a law came into force in the Free City of Danzig which enables women over 30 and men over 45 to undergo an annual examination for malignant disease free of cost to themselves It also provides for the creation of an administrative body to combat cancer by educational activities and otherwise The new law requires that treatment of the disease shall be in the hands of doctors only, treatment by correspondence and other irregular and unethical methods being forbidden Early notification is imposed on the practitioner who diagnoses cancer, and the cost of diagnosis is to be borne by the administrative body in question In a review of the considerations behind this new legislation Redenz[1] quotes instructive figures from Mecklenburg where a system of voluntary notification of all new cases of malignant disease has been started From April, 1937, to April, 1938, in this community of some 800,000 souls, 1040 women and 823 men were notified as suffering from cancer, in other words, the annual incidence was 0 23 per cent These cases were classified in two main groups according as the lesion was or was not accessible to palpation and inspection In the first group there were only 226 men but 611 women, whereas in the second group there were 597 men and only 331 women (The reason why these figures do not tot up to the score of those already mentioned is that in a few cases the exact seat of the disease was unknown) The classification shows the relatively unfavourable situation of men as regards the frequency with which they suffer from deep-seated cancers

Redenz, who is in charge of the State Maternity Hospital in Danzig Langfuhr, writes as an enthusiastic supporter of the new law and hopes it will prove a model for similar legislation elsewhere

1 Redenz, E., *Disch med Wschr* May 26, 1939 p 851

V.D TREATMENT DURING MILITARY TRAINING—The men who are being called up as liable for service under the Military Training Act 1939, may well include patients receiving treatment for venereal disease by private practitioners As it is desirable that the treatment should not be interrupted information regarding each case should be available to the medical board undertaking the examination and details of previous treatment should be made known to the medical officer at the depot where the patient is called up

The Ministry of Health does not think it practicable to circularise all practitioners, but considers it would be helpful if medical officers of health instructed those distributing arsenobenzene compounds to practitioners, and pathologists doing tests of specimens for private practitioners to send with the supply of the compound or with the report that a specimen is positive a request that, in the event of a patient being called up under the act, the practitioner should furnish him with particulars of the case on form V 15 Copies of the form can be had from the nearest V D treatment centre

PREVENTION AND TREATMENT OF PUERPERAL SEPSIS

DUE TO HÆMOLYTIC STREPTOCOCCI

BY DUGALD BAIRD, M.D Glasg., F.R.C.O.G.
PROFESSOR OF MIDWIFERY IN THE UNIVERSITY OF ABERDEEN

ALEXANDER M. MICHIE, M B Aberd., D P.H.
SENIOR RESIDENT PHYSICIAN AT THE CITY HOSPITAL, ABERDEEN; AND

ROBERT F. MACDONALD, M B Aberd.
RESIDENT PHYSICIAN AT THE HOSPITAL

THE incidence of puerperal sepsis due to hæmolytic streptococci depends on the presence of the organism at the time of labour, the general resistance of the patient, and to some extent the amount of trauma sustained Although better obstetrics will lessen damage to the genital tract, and good antenatal care will do much to improve the patient's resistance, the most important single factor is probably the presence of the hæmolytic streptococcus in the genital tract at the time of delivery.

It has been shown that most of the deaths from puerperal sepsis are caused by the hæmolytic streptococcus group A, and that this organism is absent from the genital tract before labour begins. Every effort should therefore be made to keep it from entering the genital tract while labour is in progress. This can be done by asepsis and antisepsis, the use of masks, and the exclusion of carriers of streptococci from the labour-room All these precautions should be taken in every case, so that if one barrier breaks down there will still be others. For example, while an efficient mask may prevent spread of infection for a short time, it may be a source of danger when the wearer is in attendance on the case throughout a long labour and he becomes unmindful of it.

EXCLUSION OF CARRIERS

In Aberdeen Maternity Hospital during the year 1938 stringent precautions were taken to prevent carriers of streptococci from attending patients in labour This involved the examination of all students and pupil-nurses entering upon training and the re-examination of anyone with signs of infection in the upper respiratory tract Where hæmolytic streptococci were found, the carrier was sent to a laryngologist, and where he discovered chronic inflammation or a history of recurrent attacks of tonsillitis, removal of the tonsils was recommended Where the nose and throat were reported healthy and the organisms were scanty, gargling or painting with antiseptics was carried out and the student or nurse allowed to proceed with training. The following are the findings for the year 1938.

Fifteen swabs were taken from 7 members of the medical staff, of whom only 1 was shown to have hæmolytic streptococci. His tonsils were reported to be enlarged and unhealthy, and tonsillectomy was performed No streptococci were found at a subsequent examination. A mild infection of the upper respiratory tract developed in 4 doctors, but none was due to hæmolytic streptococci.

Fifty-four swabs were taken from 49 members of the nursing staff, of whom 5 were shown to have hæmolytic streptococci. Of these, 2 had unhealthy tonsils, and the streptococcus belonged to group A. Tonsillectomy was performed, and in both cases swabs taken later did not show any streptococci. The other 3 cases showed only a few colonies of streptococci, and grouping was not done. The tonsils appeared to be healthy, and after local treatment for a few days the streptococci disappeared. The nurses were all allowed to proceed with their training. Infection of the upper respiratory tract developed in 4 members of the nursing staff. in 1 the infection was due to a hæmolytic streptococcus, but the organism disappeared after local treatment of the throat.

Eighty-two swabs were taken from 71 students, of whom 8 were shown to have hæmolytic streptococci. In 1 case the tonsils showed chronic inflammation, and local treatment did not clear up the infection. The student was then given sulphanilamide 1 tablet (0 5 gramme) three times daily for five days, after which a swab did not show the organism. In the other 7 cases the tonsils were clinically healthy, and, since the organisms were not present in large numbers, the students were allowed to go on with their training but were warned to be extremely careful in their technique.

Among 773 booked cases delivered in the hospital in 1938 there was 1 case of notifiable pyrexia due to the hæmolytic streptococcus This woman had been in labour for eight hours before she was admitted to hospital, and none of the members of the hospital staff who were in contact with her was a carrier of hæmolytic streptococci She did not have the organism in her throat The temperature settled quickly under treatment. During the same year the staff attended 464 other cases, made up of 260 booked district cases, 7 emergency district cases, and 197 emergency hospital cases, 5 of them developed notifiable pyrexia due to a hæmolytic streptococcus Although the numbers are too small for definite conclusions to be drawn, they suggest that the risk of infection with the hæmolytic streptococcus is much less when the whole labour is conducted inside the hospital. It may be objected that the two groups are not comparable, since the smaller one contains 204 emergency cases, many of which were abnormal; but against this the booked district cases are specially selected parous women, who had had previous easy labours, further, many of the booked cases delivered in the hospital were sent there early in pregnancy because of expected difficulty. Therefore the proportion of women having difficult delivery was about the same in both groups In any case, infection with the hæmolytic streptococcus does not depend so much on the type of labour as on the risk of exposure to the organism.

In an attempt to throw more light on the problem, an analysis of all cases of puerperal pyrexia in the city and county of Aberdeen requiring hospital treatment in 1938 has been made. This has been possible because all such cases are treated in the city fever hospital During 1938 32 cases were admitted (excluding abortions) in which the infecting organism was a hæmolytic streptococcus The total number of births in the area, less those in the maternity hospital, was 5387. This gives an incidence of notifiable pyrexia due to hæmolytic streptococcal infection of 1 in 168 as compared with 1 in 773 in the maternity hospital These findings agree with the figures which have been published by other hospitals recently and support the view that the risk of the patient developing a puerperal infection due to a hæmolytic streptococcus is at the moment much less in a well run maternity hospital than it is in her home.

EFFECT OF CHEMOTHERAPY

It was thought that an analysis of the maternal deaths might reveal whether the use of sulphanilamide had caused any reduction in the death rate For this purpose the maternal deaths in the city and county area of Aberdeen in the last eight years have been investigated They have been divided into two groups 1931–35 and 1936–38 inclusive Table I shows a reduction in the total death rate from 6 2 to 4 6 per 1000 This is due to a large extent to a fall

TABLE I—MATERNAL DEATHS IN THE CITY AND COUNTY OF ABERDEEN, 1931–38

Year	Births	Maternal deaths	Death rate (per 1000)	Death rate due to sepsis (per 1000)	Deaths from sepsis	Average yearly deaths due to haem strept
1931–1935	30,172	190	6 2	2 05	61*	7 6
1936–1938	17,527	82	4 6	1 02	18†	2 66

* 38 due to haemolytic streptococcus
† 8 due to haemolytic streptococcus
The total maternal death rate is high owing to the fact that all deaths from intercurrent disease, such as pneumonia, heart-disease, and malignant disease in pregnant women are included If such deaths were excluded, the death rate for 1936–38 would be 3 5 per 1000 instead of 4 6

in the death rate from sepsis It fell from 2 05 to 1 02 per 1000 On further analysis of the cases of sepsis it is seen that the biggest fall in the death rate is in the cases due to the haemolytic streptococcus There were 38 deaths from sepsis due to haemolytic streptococci in the first five years (1 26 per 1000) and 8 deaths in the next three years (0 45 per 1000) As regards the cases of sepsis due to other organisms, there were 23 deaths in the first five years (0 76 per 1000) and 10 deaths in the next three years (0 57 per 1000)—not such a sharp fall

While it still remains impracticable to conduct all midwifery cases in hospital, it is thought that many deaths might be prevented by the use of the sulphonamides To ascertain to what extent the improvement in the results of treatment of puerperal sepsis is due to the administration of sulphonamides, and in which type or types of infection this has taken place, a survey of all cases admitted to the puerperal ward at the Aberdeen city fever hospital during the years 1931–38 inclusive has been made in table II

TABLE II—CASES OF PUERPERAL SEPSIS ADMITTED TO ABERDEEN CITY FEVER HOSPITAL, 1931–38

Organism responsible for death	Group A Jan 1931–June 1936			Group B June 1936–Dec 1938		
	Cases	Deaths		Cases	Deaths	
Haemolytic streptococcus	240	46	(19 2%)	96	8	(8 3%)
Anaerobic streptococcus	313	7	31 (9 9%)	104	2	10 (9 6%)
Staphylococcus		9			4	
B coli		7			1	
Miscellaneous		8			3	
Total	553	77	(11 9%)	200	18	(9 0%)

This hospital admits patients with puerperal sepsis from a rather larger area than the city and county of Aberdeen, thus explaining the slight difference in figures from those in table I

During this period 753 patients with puerperal sepsis were admitted The patients have been divided into two groups Group A consists of 553 patients admitted during the period January, 1931, to June, 1936, and group B consists of 200 patients admitted during the period July, 1936, to December, 1938, all of whom had sulphonamide treatment Of the 553 patients in group A 77 died, giving a case-mortality of 13 9 per cent Of the 200 patients in group B 18 died, giving a case mortality of 9 0 per cent This shows that a reduction in the total case-mortality has taken place since the introduction of sulphonamide therapy

A further analysis shows that of the 553 cases comprising group A 240 were due to infection by haemolytic streptococci, with 46 deaths (19 2 per cent) Of the remaining 313 patients with infections due to other organisms 31 died (9 9 per cent) In group B 96 out of 200 patients were infected with haemolytic streptococci, 8 (8 3 per cent) of whom died, and of the remaining 104 with infections due to other organisms 10 died (9 6 per cent) Thus it is evident that, whereas the case mortality of infections due to organisms other than the haemolytic streptococcus shows only an insignificant difference (9 9 per cent) in the first group as compared with 9 6 per cent in the second), there is a fall in the case mortality from 19 2 to 8 3 per cent in infections with haemolytic streptococci

TABLE III—STREPTOCOCCAL PUERPERAL SEPSIS CLASSIFIED ACCORDING TO BASE OF DELIVERY, BEFORE AND AFTER THE INTRODUCTION OF SULPHANILAMIDE THERAPY

Year	Streptococcal cases	Easy deliveries		Difficult deliveries	
		Recoveries	Deaths	Recoveries	Deaths
1931	34	22	2	6	4
1932	47	27	3	10	7
1933	23	12	4	4	3
1934	51	28	7	13	3
1935	54	31	3	14	6
1936	31	17	1	12	1
Total	240	137	20 (12 7%)	59	24 (28 9%)
1936	19	8	0	0	2
1937	40	22	1	15	2
1938	37	17	1	17	2
Total	96	47	2 (4 1%)	41	6 (12 8%)

It is generally recognised that the risk of a puerperal infection increases in proportion to the amount of manipulation carried out and to the extent of the local laceration and tissue damage sustained To ascertain the effect of local trauma on prognosis it was decided to divide the cases into two groups (1) difficult labours, including all forceps deliveries, manual versions, craniotomies, and spontaneous deliveries where there was evidence of much tearing, and (2) easy deliveries, including spontaneous deliveries and cases in which it could be ascertained that no surgical intervention had taken place It was assumed that the local trauma would be more severe in the first than in the second group

Table III shows that, before the introduction of sulphonamide treatment, there were 157 cases of haemolytic streptococcal infection following easy delivery, with 20 deaths (12 7 per cent), and 83

following difficult delivery, with 24 deaths (28·9 per cent.) After the introduction of sulphonamide treatment there were 49 cases of hæmolytic streptococcal infection following easy delivery, with 2 deaths (4·1 per cent.), and 47 following difficult delivery, with 6 deaths (12·8 per cent.) As a result of sulphonamide treatment, therefore, a striking fall in the case-mortality of hæmolytic streptococcal infection has taken place, irrespective of the type of labour but more obvious where the labour has been easy. There has been a relative fall in the proportion of cases of puerperal sepsis due to the hæmolytic streptococcus after easy delivery admitted to hospital. This may be due to the fact that patients with sepsis after easy delivery are quickly cured with sulphanilamide and do not require hospital treatment. There has been a fall in the total number of cases admitted to the puerperal wards in the last two years. It is clear therefore that in spite of sulphonamide treatment the prognosis is poor in hæmolytic streptococcal infection when there has been extensive local trauma.

CASE-RECORDS

It was thought worth while to summarise the case-histories of the eight fatal cases in the hæmolytic streptococcal group, treated with sulphonamide, and to ascertain what were the chief factors responsible for the deaths.

CASE 1.—A primipara, aged 26, admitted to hospital in 1936 on the fifth day of her puerperium. There was a history of a difficult forceps delivery, a stillborn child, and a large postpartum hæmorrhage. She had a rigor on the second day of the puerperium. On admission she was very ill, with signs of a pelvic peritonitis. She was also suffering from a secondary anæmia: red blood-cells 1,530,000, hæmoglobin 27 per cent. Examination revealed a severe degree of perineal and vaginal tearing.

The patient was *treated* with Prontosil rubrum (10 c.cm. of a 2½ per cent. solution intramuscularly eight-hourly) and Prontosil album (sulphanilamide) 1 g. eight-hourly. Despite treatment she developed a phlegmasia alba dolens on the ninth day of her puerperium and a streptococcal empyema on the fourteenth day. She died the following day. Blood-culture was positive to hæmolytic streptococci. At no time during the course of the illness did the patient respond to treatment. No sulphanilamide was administered before admission to hospital.

In this case the factors responsible for the fatal issue were severe trauma with postpartum hæmorrhage, delay in instituting chemotherapy, and possibly inadequate dosage.

CASE 2.—A 6-para, aged 27, admitted to hospital in October, 1936, with a history of a very difficult labour: transverse lie, attempted internal version, decapitation, and manual removal of placenta. She developed a rise of temperature on the third day. She was admitted to hospital the following day and had a rigor the same evening. She had no sulphanilamide before admission.

Treatment.—10 c.cm. of a 2½ per cent. solution of prontosil rubrum intramuscularly eight-hourly, and sulphanilamide (1 g.) eight-hourly. She died of a typical septicæmia without localising signs on the tenth day of her puerperium.

The important factor in this case was probably poor antenatal and intranatal care, resulting in unnecessary trauma and massive invasion of the tissues.

CASE 3.—A 10-para, aged 40, had had a septic abortion when she was four months pregnant, and was admitted in 1937 on the seventh day of the puerperium. She had been previously in poor general health, and had a spontaneous abortion after bleeding five days. No medical man was consulted. She had had several rigors before assistance was sought. On admission she was very ill and suffering from a septicæmia. Three hours after admission an embolus entered her *left* retinal artery, and within seventy-two hours the eyeball ruptured and the lens was extruded.

Treatment.—Prontosil rubrum 10 c.cm. of a 2½ per cent. solution intramuscularly twelve-hourly and sulphanilamide 3 tablets eight-hourly. She died on the fourth day in hospital.

In this case there were three factors: no antenatal care; delay in sending for medical aid, and delay in instituting chemotherapy.

CASE 4.—A primipara, aged 34, admitted in 1937 on the sixth day of her puerperium. She had had her membranes artificially ruptured. She was delivered by forceps, having been in labour only three hours. There were numerous rigors before admission to hospital.

Treatment.—Sulphanilamide 1½ g. four-hourly by mouth and 10 c.cm. of prontosil rubrum intramuscularly eight-hourly. Despite intensive treatment she showed no response and died of a pneumonia seven days after admission.

In this case there was unnecessary trauma due to too early application of forceps and delay in instituting chemotherapy.

CASE 5.—An 11-para, aged 41, admitted to the maternity hospital in 1937 with a history of a central placenta prævia and much hæmorrhage. Bipolar version was performed. The child was stillborn. The patient developed a rise of temperature on the third day and was admitted to the City Fever Hospital six days later.

Treatment.—On admission she was given sulphanilamide (1 g.) by mouth eight-hourly. Streptococci were demonstrated in the blood-stream on the sixteenth day of her puerperium. The dose of sulphanilamide was increased to 1½ g. four-hourly, and prontosil rubrum 10 c.cm. was administered intramuscularly eight-hourly. By the thirtieth day her blood-culture was sterile, and sulphonamide was discontinued. On the thirty-fifth day she was discovered to have a complete agranulocytosis, and despite three blood-transfusions she died on the thirty-seventh day.

In this case death was due to faulty treatment of the placenta prævia and to overdosage of sulphonamides.

CASE 6.—An 8-para, aged 28, admitted to hospital in 1938 with a history of having been eight hours in labour with a breech delivery. The child was born before assistance was obtained. The patient had a rigor on the first day of her puerperium and was admitted on the second day, when she was found to have a septicæmia.

The *treatment* adopted was sulphanilamide 1 g. by mouth four-hourly. No improvement was observed by the twelfth day, when in addition to oral prontosil she was given prontosil rubrum (10 c.cm. of a 5 per cent. solution) intramuscularly eight-hourly. On the eighteenth day she developed a phlegmasia. The administration of sulphonamides was continued until the thirty-fourth day without the slightest response. She died on the forty-second day, there being evidence of numerous pulmonary infarcts at necropsy.

There is nothing here to account for the failure of chemotherapy.

CASE 7.—A primipara, aged 20, admitted to hospital in 1938. Labour lasted eighteen hours, and she was delivered by forceps of a live child. The patient was being looked after by a midwife. She developed a pyrexia on the first day of her puerperium but was not admitted to hospital until the seventh day. No treatment had been given.

Treatment—Sulphanilamide 1 g eight-hourly was administered until the fifteenth day, when a small piece of placental tissue was removed Her blood-culture was positive the following day, when the dosage was increased to sulphanilamide 1 g by mouth four-hourly and 10 c cm of a 5 per cent solution of prontosil rubrum eight-hourly The same day she was given a transfusion of one pint of blood Despite intensive treatment carried on for a further twenty-six days, she developed a septic streptococcal arthritis of both wrist-joints and one knee-joint She died of exhaustion on the sixty-third day of her puerperium

In this case a piece of placental tissue was left inside the uterus, and sulphanilamide treatment was not begun until the seventh day post partum

CASE 8—A 10-para, aged 40, admitted to hospital in 1938. She was in very poor health during her pregnancy She was a midwife's case, but the delivery had to be assisted by a low-forceps operation after she had been seven hours in labour She had a rigor on the second day of the puerperium, but the doctor was not recalled until the seventh day, when she was admitted to hospital No sulphanilamide was administered before admission

Treatment—She was given sulphanilamide 1 g by mouth four-hourly On the tenth day she was also given 10 c cm of a 5 per cent solution of prontosil rubrum intramuscularly eight hourly By the fifteenth day her blood-culture was sterile and her temperature and pulse-rate had almost settled On the seventeenth day, however, the temperature again rose and her blood-culture again became positive M & B 693 1 g four-hourly was substituted for the prontosil on the twenty second day without success, and she died on the thirty-fourth day of her puerperium

In this case there was unjustifiable delay in sending the patient to hospital and instituting chemotherapy

COMMENTS

On consideration of the above case histories we think that it would be fair to conclude that antenatal care was deficient in cases 2, 3, and 8 Better supervision during pregnancy might have prevented the malpresentation in case 2 and thus have avoided the subsequent manipulations. Case 3 did not consult a doctor during her pregnancy, and her condition must be considered to be unavoidable, illustrating the need for increasing educational facilities and for emphasising the dangers of abortion in unfavourable circumstances In case 8 supervision during the antenatal period would possibly have led to improvement in her general condition and thus have increased her resistance to infection

Better facilities during labour in cases 1, 4, 5, and 6 might have prevented infection In case 1 the severe perineal and vaginal lacerations in conjunction with postpartum hæmorrhage predisposed to infection Case 4 had obviously been mismanaged, forceps having been applied in a primigravida only three hours in labour In case 5 cæsarean section might have been considered, but this depended on the amount of interference before admission to the maternity unit and on other factors Case 6 illustrates the necessity for a qualified person to be present at every labour to avert the danger of the woman either infecting herself or being infected by the unskilled attentions of a neighbour

Better supervision during the puerperium might have led to earlier hospitalisation in cases 1, 3, 4, 7, and 8 We think that all will agree that there was obvious delay between the first signs of fever and admission to hospital Experience shows that the longer the appropriate measures are delayed, and the more advanced are the pathological changes, the less chance have specific measures of effecting a cure

As regards treatment after admission to the puerperal ward at the City Hospital, Aberdeen, it might be suggested that in cases 1 and 2 the dose of sulphanilamide was too small However, at that time sulphanilamide treatment was in its very early stages, and an attempt was being made to assess the optimal dosage A fatal issue in case 3 was unavoidable with any form of treatment Despite adequate doses of sulphanilamide in cases 4, 6, 7, and 8, the drug did not control the infection Circumstances were particularly favourable in case 6, although the patient was suffering from septicæmia, for she was admitted on the second day of her puerperium and appropriate treatment was instituted early In cases 4, 7, and 8 circumstances were not quite so favourable, fever having begun several days before admission It is more than possible that types of hæmolytic streptococci vary in their susceptibility to the drug Case 5 was rather an unfortunate one, the infection having been controlled, but the patient dying of an agranulocytosis following relatively heavy dosage of sulphonamides

CONCLUSIONS

In a well run maternity unit, where strict control of all contacts during labour and the puerperium is obtainable, the incidence of streptococcal sepsis can be reduced to a very low level.

During the past three years the death rate due to puerperal sepsis has been much reduced, particularly in patients infected with hæmolytic streptococci The improvement is mainly due to treatment with sulphonamides

The chief factors predisposing to failure with sulphonamide treatment are closely related to the extent of trauma, the late institution of adequate and appropriate therapy, and the degree of advancement of the pathological changes when first seen

SUMMARY

(1) The incidence of puerperal sepsis due to hæmolytic streptococci depends on the presence of the organism in the genital tract during labour, the patient's resistance, and the amount of trauma sustained

(2) Most of the deaths from such sepsis are caused by the hæmolytic streptococcus group A, absent from the genital tract before labour

(3) The access of the organism to the genital tract during labour can be prevented by asepsis, antisepsis, the use of masks, and the exclusion of carriers of streptococci from the labour room

(4) The risk of infection with the hæmolytic streptococcus is much less when the whole labour is conducted in hospital

(5) The maternal deaths in Aberdeen are analysed in two periods—1931–35 and 1936–38 There was a fall in the death rate from 6·2 to 4·6 per thousand, due mainly to a fall (from 2·05 to 1·02 per thousand) in the death rate from sepsis, the biggest fall in cases of sepsis being in those due to the hæmolytic streptococcus

(6) An analysis of the cases of puerperal sepsis in Aberdeen in two periods—before and after the introduction of sulphonamide therapy—shows a fall in the total case mortality from 13·0 to 9·0 per cent, and a fall from 10·2 to 8·3 per cent in the case mortality of sepsis due to the hæmolytic streptococcus

(7) To decide the effect of trauma on the incidence of puerperal sepsis, cases were analysed in two

groups according to whether delivery was easy or not It was found that with easy delivery the case-mortality was 12 7 per cent and with difficult delivery 28·9 per cent before the introduction of sulphanilamide, and 4 1 per cent with easy delivery and 12 8 per cent with difficult delivery after the introduction of sulphanilamide therapy. Therefore, in spite of treatment with sulphanilamide, the prognosis is poor in hæmolytic streptococcal infection in the presence of extensive local trauma.

(8) Eight fatal cases are summarised, and the chief factors responsible for death are pointed out.

WAR NEUROSES

THE Ex-Services Welfare Society held its annual medical conference on July 7, with the president, Prof EDWARD MAPOTHER, in the chair. The subject of discussion was the incidence of war neuroses in civilians and in each of the armed forces The chairman, in opening, asked for practical suggestions for the prevention of neuroses, and for answers to basic questions. What can be done to reduce mental stress? How far can individual predisposition be detected and the susceptible put to forms of service in which they can be useful? How can the causal factor of personal advantage be prevented by raising morale and by taking profit out of the neuroses? A new problem in a future war may, he said, be an increase of neurosis among civilians There is no evidence that any neurosis was caused by air-raids in the last war; on the other hand, future air-raids may be far more trying Much will depend on the efficiency with which our own aircraft repel raiders Defending gunfire is nearly as productive of neurosis as enemy bombs

SERVICE VIEWS AND EXPERIENCE

Surgeon Vice-Admiral P T NICHOLLS said that according to data given by Beaton admissions at Chatham for neurosis and psychosis rose steadily through the late war relatively to the numbers of the personnel Forty-one per cent were classed as psychoses, but the proportion today would perhaps be smaller Of the three neurotic groups—neurasthenia, hysteria and shell-shock, the first was by far the largest and 95 per cent of the cases in it were suffering from anxiety states Many anxiety cases closely resembled cases of Graves's disease Hysteria was much rarer than in the Army, perhaps because sailors as a class are more independent and less suggestible than soldiers Most neurotics were lost to the service In a future war the problem might be made more severe by insecurity from air-raids in harbour and by anxiety for the safety of wives and families The figures would be increased by flying stress neurosis in the Fleet Air Arm Steps should be taken to eliminate men with a constitutional tendency to neurosis, but it is not practicable to examine all troops psychiatrically or to attempt to restore neurotic patients to duty by psychotherapy. Every effort should be made to send psychiatric casualties quickly to a centre where expert diagnosis is available, and then to dispose of them suitably. This plan may present great difficulty among sailors serving in remote parts of the world There is a serious shortage of medical officers capable of performing this service

Major-General ROBERT PRIEST said that the Army has already begun to apply many of the points suggested by Prof Mira on the basis of his Spanish experience All officers receive lectures on mental disorder and impart their knowledge to the troops The question of selecting personnel and deciding, on the history of each man, whether he shall be employed in front or back areas is still under discussion If the officers are prepared by special notice, it is practicable to discharge patients before they are completely cured The incidence of nervous disorder would be much reduced by keeping up the strength of the forces and of the population by good and regular feeding Preliminary training—for example, by black-outs—should be applied energetically to the civilian population to eliminate the all-important element of surprise

Group-Captain H L BURTON gave figures for the incidence of nervous disorder in the Royal Air Force in 1937: in a total force of 60,000 the admissions for psychoneurosis were 125, of whom 41 were invalided—an incidence of 2 1 per thousand There were 24 cases of mental disease Mental and nervous illness is the commonest cause of invaliding in the Royal Air Force, perhaps because the standard of criticism is so high. Flying personnel are weeded out early in their training, and the incidence among fully trained flying staff is low. Neurosis is not closely connected with the duties of a patient, but rather with conflict. Most patients show a marked lack of confidence, but often the only prominent symptom is a general failure to perform duties efficiently. Among men classed as unlikely to make good fliers, temperamental defects account for 80 per cent These may be combined with psychomotor defects and are usually detected early A second group realise that they cannot cope with the faster machines they meet in later training A third group, breaking down after a career of some length, do so from unexplained loss of confidence, from a definite event such as an accident, or from private trouble Some develop a growing feeling that it is only a matter of time before disaster overtakes them The precise classification of nervous disorder is not regarded as important, for most men who break down are lost to the service Breakdowns among the lower ranks from psychological inferiority have increased. It is difficult to decide whom to discharge, for it is bad to discharge too freely. Some method of eliminating unsuitable recruits is needed

Among the flying personnel the watchword is prophylaxis All medical officers receive a brief course in psychology applied to their particular work They observe their personnel constantly for signs of stress and suggest modifications of the work where necessary They encourage men to discuss their troubles, and offer advice Very little intensive psychotherapy is performed: few medical officers can give it, and there is no conviction of its value In war-time the scheme of treatment would consist of a series of filters The first is the medical officer of the unit; the second is the consultant, to whom doubtful cases would be sent Treatment would be short and mild. men would either go straight back to duty after a rest and explanation, or be given a short period of leave, or be sent to a special hospital for psychotherapy. Prognosis would depend on the extent to which the patient had acquired control of his emotional level by his intellect or sentiment. Men should not be invalided back to civilian life, but retained in uniform and subject to duty unless they were quite hopeless and incompetent

Dr E PRIDEAUX said that during the war about 30 per cent. of those who broke down mentally were constitutional neuropaths These were mostly

persons who had been in some kind of clerical occupation and had been conscripted, their physique was inferior and they broke down at home Hysterics broke down after a short period of service overseas, anxiety patients after perhaps a year and a half Of the psychological inferiors, who would probably today be called high grade feeble minded, nearly all went overseas and a third of them served through the whole war, mostly in departmental units but quite usefully

Prof EMILIO MIRA (chief psychiatric inspector to the Spanish Republican Army) distinguished three periods in the Spanish war During the first period service was voluntary and the element of conflict was absent There were no figures, but the incidence of nervous troubles was probably low In the second period the army was organised and there was a high casualty-rate The incidence of discharge for war neurosis was 1 5 per thousand Soldiers from the North of Spain resisted neurosis better but suffered from it worse The incidence among front line troops was strikingly low, probably because their morale was better Its most common form was conversion hysteria, which often yielded to a few days' treatment Anxiety states were common, but usually developed into hysterical syndromes The third period was marked by shortage of food, the conscription of very young troops, and lack of confidence in victory There was no great increase in neurosis, as the psychological selection was good and front line troops were not psychiatrically infected The highest incidence was among anti aircraft units and sanitary services, the second among infantry and transport Symptoms among flying officers were due rather to exhaustion than to neurosis Nervous breakdown was very rare in the 10th and the 15th Corps, which consisted of Communists with strong political sympathies The source of neurosis being fear, a strong enthusiasm will counteract it Prof Mira considered that the best antidote to war neurosis is a campaign of political information to inspire devotion to the object for which the war is being fought This is particularly necessary in country districts There was no great increase in neurosis among civilians under totalitarian conditions As soon as social order and organisation were established, the frequency of nervous and mental disorder fell to the normal peace time level.

Dr E GUTTMANN said that as far as he could judge from the scanty German statistics available, acute neurotic reactions in front line troops of the German army in the late war were rare The incidence in the navy was about half that in the army, and the proportion of neurosis to psychosis was as ten to seven Air raids on civilians did not appear to cause any increase in admissions to psychiatric clinics, an increase of anxiety was, however, noticed among inpatients He gave some statistics from earthquake districts

PROPAGANDA AND DISCIPLINE

Dr A MCGLASHAN said that the two main psychological effects of war flying on a pilot are to cause extravagance of behaviour and lability of the emotional state A pilot during an expedition is intensely suggestible, for he is very young, he is alone and unsupervised, and his only task is to discharge his bombs It is difficult to be heroic about dropping bombs on women and children, and pilots have an instinctive distaste for the work Psychological ingenuity could be used to take advantage of the mental vulnerability of the pilot and induce panic in him His suggestibility should be intensified by propaganda and worked upon by suitable methods during air raids A committee of psychologists could probably devise effective methods

Dr THOMAS BEATON said that an unusual number of patients attended his outpatient clinic in Portsmouth last September The number may rise in a war through the effect of general tension on existing nervous instability High emotional tension did not produce neurosis or psychosis in any of the casualties of the Zeebrugge raid, and will only produce mental disturbance in predisposed persons Anxiety neurosis in the Navy was really due to exhaustion as the end result of protracted stress, and very few cases could be restored to duty A large proportion showed a definite enlargement of the thyroid A high proportion of psychotics were cured Neurotics must have security but not comfort good discipline is essential, and success would largely depend on the popular attitude to the neurotic being sound He must not be pampered the term "shell shock" was one of the most important causes of the condition in the last war Dr Beaton said he was a little frightened of the responsibility which courts, schools, administrators and now the fighting services tend to throw on the psychiatrist, who is only a human being He can pick out a definite psychotic but cannot really claim to assess the possibilities of neurosis in a soldier or sailor

Dr IVOR DAVIES pointed to the very high incidence of minor neurosis in the population today. Half the outpatient cases in the Cardiff Royal Infirmary are functional, and these do not receive treatment Many of them are cases of gastric neurosis The country should deal with them in peace time, for in a war many of them would become ineffective Hyperpietics are potential psychopaths Thyrotoxics would be very largely incapacitated in a war There is already a high incidence of goitre, which would be likely to become toxic under continuous threat of bombing Allergic patients and sufferers from chronic bronchial catarrh easily develop neurosis The schools should devote more attention to teaching children self control and self reliance—lessons they do not always learn at home A R P shelters should contain some persons with a knowledge of psychology, to deal immediately with neurotics They could be selected from health visitors, social workers, sanitary inspectors, clergy, or voluntary aid detachments

Dr W M MCALISTER thought that the prospect of nervous disorder in a war is not as bad as some people fear Panic due to air raids does not necessarily cause a rise in mental disorders The public must be educated to prepare them for the situations which may arise

Dr C S MYERS, F R S, recalled that in the last war the incidence of neurosis in badly disciplined regiments was high, in well disciplined regiments very low The incidence might be reduced by training fighters in a proper attitude to the enemy Education should be framed with the object of counteracting the air pilot's objection to bombing women and children Save for a few exceptions, no pension should be allowed for psychoneurotic disability The vocational psychologist could probably apply his special experience to the problem of selection, and should take part in training psychiatrists

Dr J D STIRSON said that most of the would be flying officers who break down early are of the sub intellectual type Hyperthyroidal patients are unlikely to make good patients When once a medical officer has been called in and the suggestion

of nervous disorder has been made energetic action must be continued until cure or definite disposal.

Dr M W BULMAN remarked that, if Joan Grant's novel "Winged Pharaoh" could be believed, the Egyptians knew methods of psychologically disabling their enemies seven thousand years ago. The small incidence of neurosis in the Navy may have been due to the fact that the stress was intermittent and the personnel were picked regular volunteers who were accustomed to the work and were not contaminated by conscripts. Conscripted men should have an opportunity to choose their units, for unconditional compulsion is a cause of neurosis. Similarly, civilians should be allowed to choose whether they will be evacuated or not.

Dr HENRY YELLOWLEES thought that the sailor was spared much anxiety by the comforting reflection that if he were killed it would be in company with many others. The soldier had to face being picked out from among his comrades. Education in the possibility of war neurosis might do as much harm as sex education has done, and might train young people to expect a psychological disaster. The objection to the use of vocational psychology is, he considered, that war is not a vocation, and even the vocational psychologist could not turn the psychological energy of the whole country into channels which no-one would choose if he could help it.

Dr GEORGE GORDON deprecated a defeatist attitude towards the possibility of selecting personnel. Much can be done, he said, by using the enormous data on invalidism which already exists, and by testing for such reactions as dermatography and such signs as hyperthyroidism and disturbances of the autonomic system.

Prof. MAPOTHER, in closing the discussion, said that it would be impracticable to deny compensation to psychoneurotics, but it should be refused during a war, and they should not be discharged.

MENTAL HOSPITALS ASSOCIATION

THE annual meeting of this association was opened by the LORD MAYOR OF LONDON at the Guildhall on July 6. Mr. J W BLACK, J.P. (Leicester and Rutland), took the chair.

Divorce for Insanity

Sir LAURENCE BROCK, chairman of the Board of Control, in an address to the meeting said that visiting committees and mental-hospital officers are disturbed by the uncertainty of the legal position of a patient under the Matrimonial Causes Act, 1937. A patient may be divorced if he is incurably of unsound mind and has been continuously under care and treatment for at least five years immediately preceding the presentation of the petition. A person is under care and treatment while he is detained in pursuance of any order or inquisition under the Lunacy and Mental Treatment Acts. In the case of Shipman v. Shipman (1938), said Sir Laurence, it was not seriously argued that the patient was likely to recover, but she had been sent from time to time to a relative, sometimes for periods running into months, and she had spent just under 400 days outside the hospital during the statutory five years. Moreover, the visiting committee had invented a new and wholly extrastatutory form by which they had allowed her to leave the hospital on "provisional discharge". The substance of the judgment in this case appears to be that short absences, such as week-end leave, may be disregarded, but there must come a point at which absence on trial will break the continuity of the five years and do away with the right to divorce.

In certain cases the medical officer may be put in an embarrassing position, but the scope of the Shipman judgment has been somewhat narrowed by the observations of the president of the Divorce Court in Green *v.* Green (1939). In that case the patient had been sent to a home maintained by the Mental After Care Association: as he had been under some kind of control the court held that the continuity of the five-year period had not been broken. The president regarded as important the fact that the home was exclusively occupied by London County Council patients and the association were acting as agents for the council. The position of a patient who is sent to an ordinary holiday home admitting patients from different hospitals is still extremely obscure. The Board of Control have issued a circular (No. 861) on the Shipman judgment. The duty of the superintendent of a public mental hospital is clear: he must be guided solely by the interests of the patient and owes no duty to the other party to the marriage. While it would be unwise to do anything which might obstruct divorce proceedings, he ought not to be deterred from doing his best for the patient by any considerations of possible ulterior consequences to other people. The medical officer in charge of a licensed house, though no less anxious to do his best for the patient, may find his work undone by the petitioner exercising his or her right to withdraw the patient when the doctor asks consent to give leave of absence on trial. Sir Laurence hoped that the legal obscurities of this question may be cleared up before long. He expressed the personal opinion that some amendment of the part of the 1937 act will have to be made on one of two lines: either the right to divorce must be made to depend on a certain period of continuous treatment, or the act must be brought into line with the Scottish act and contain a presumption that the patient is incurable after a certain period of continuous treatment unless evidence to the contrary is produced. In any case, absence on holiday or on trial ought not to be held to break the continuity of the five-year period.

Dr. T. C. GRAVES (Birmingham), in opening a discussion on the Matrimonial Causes Act, 1937, in relation to mental-hospital practice, pointed out that a period spent as a temporary patient may not count in the five years' detention period, for the temporary recommendation may not be an "order" under the act. If it is legally an order, the original purpose of creating it is defeated. The act turns mental hospitals into places where not only a patient may be "detained" but where he may lose his life partner and perhaps his only legal friend within a few years. The stigma of the mental hospital is undoubtedly increased, and the act may induce relatives to apply for discharge before a patient is well enough. Visiting committees should see the patients who may be respondents to a divorce petition, and review the circumstances of their illness and detention. This review is of great support to the medical officer who has to give evidence. The distinction between voluntary and temporary patients on the one hand and certified patients on the other, Dr. Graves maintained, is wholly arbitrary, has no medical basis, and under the new act is grossly unfair. The Mental Treatment Act, 1930, should

be amended so that all patients except really voluntary admissions come into mental hospitals on a temporary recommendation, with a maximum of two years for treatment according to the knowledge and capacity of modern medicine and surgery and without the present obstacles to temporary treatment The need for further residence after the initial term should be decided by the Board of Control

Many general paralytics live on for years after modern treatment How, asked Dr Graves, is such a patient to be protected against divorce by the partner who gave the patient syphilis perhaps twenty years before, and what evidence will be accepted that the petitioner is responsible for the patient's condition? A petitioner may also have been guilty of "such wilful neglect or misconduct as to have conduced to the unsoundness of mind" by neglecting the patient, interfering with treatment or preventing others from helping or treating the patient It may be advisable for the medical practitioner, before pronouncing on incurability, to state the treatment which has been given but has been unsuccessful In a grimly defended suit the practitioner might be subjected to a severe cross examination with the object of proving that the petitioner has wilfully put the patient in charge of someone who has neglected to take active measures to benefit him

When a decree of divorce has been pronounced, the doctor should not give up attempting cure, he should completely forget the legal interruption and maintain an active interest in the patient's well being and possible recovery Many patients recover after five years New agents and modes of treatment may be applied to mental disease with quite unexpected results After decree *nisi* steps may be commenced to obtain an order for the maintenance of the patient and children The guardian *ad litem*, usually the Official Solicitor, represents the patient and, if the patient recovers after divorce, will arrange to restore his/her property and rights of access to children and, where they exist, the rights to maintenance

Dr J I RUSSELL (York) said that the president of the Divorce Court, in an unreported case Crawford *v* Crawford, said he would be favourable to the suggestion that temporary treatment if extended by the Board of Control is detention under an order It happened, however, that by adjourning the case till the next session the five year period could be completed without invoking the period of temporary treatment, this course was followed, and it became unnecessary for the president to decide the point

The meeting referred the whole question of the amendment of the law to the executive committee for action, in coöperation with the visiting committees of the country

Present Situation of Mental Hospitals

In the course of his address Sir LAURENCE BROCK said that the general position in mental hospitals shows a slight but welcome improvement since last July The aggregate shortage of beds has been reduced from 3608 to just under 3000, but the position remains serious Progress at Lathom Park and Margaretting has been slow, and the proposed site of the third mental hospital has had to be abandoned owing to difficulty of drainage The position must therefore become worse in the next two or three years Steady progress, however, continues to be made in the provision of admission units and nurses' homes Even when the discharge rate is unaffected, the relapse rate falls when an early treatment centre is opened. An indirect but important advantage is the stimulating effect of the existence of modern treatment facilities on the keenness of the medical staff A keen doctor will not remain in hospital, or if he does remain he will not retain his keenness, unless he is given a fair chance of doing his best for his patients and if he knows that his new admissions have to be brought into overcrowded wards in contact with chronic and seriously ill patients

English hospitals are very understaffed, he continued, in comparison with most of the continental hospitals In the university clinic at Waldau, just outside Berne, with somewhat less than a thousand beds, the medical staff consists of a director and nine other whole time doctors Visiting committees do not always appreciate the hard work thrown upon the medical staff by an outpatient clinic. Medical staffs badly need strengthening, to enable the outpatient clinics to hold far more frequent sessions and do much more in the way of treatment Such an increase would do much to remove the reproach that many outpatient centres do very little more than diagnosis It would also reduce considerably the number of patients who have to go to mental hospitals

Dealing with air raid precautions, Sir Laurence said that in most hospitals it would not be practicable to attempt any considerable transfer of patients from one part of the building to another in the short time which would elapse between the warning and the raid, it would certainly not be practicable to attempt to transfer patients to trenches The Government will not relieve local authorities of any of the expenses of maintaining institutions, the cost of emergency precautions must fall on local funds The local authority has no more claim to relief than the employer of labour In conclusion, he said that the national emergency must not lead to any sagging down in mental health services Visiting committees should survey the field as a whole and frame a comprehensive programme, aiming wherever possible at prevention At the moment nothing is more important than the development of outpatient centres It will not add to the strength of national defence to neglect the mental health of the nation

MEDICINE AND THE LAW

A Miscarriage

AT a Chester inquest last week two doctors were criticised for failure to coöperate with the Flintshire county council's scheme for welfare in maternity cases The deceased, a married woman aged 38, had died in an ambulance on the way to hospital The two doctors had been attending her after a miscarriage They had omitted either to call in a specialist or to send the patient to hospital promptly Dr W H Grace, pathologist, who conducted a post mortem examination, stated in the witness box his opinion that the omission of the measures which the county council's scheme contemplated was responsible for the condition finally resulting in the patient's death In the coroner's view the evidence indicated the importance of coöperating in the local authority's scheme, this was a case which should have been tackled and finished at the earliest moment The jury added to their verdict of "death by misadventure" a rider that death was due to negligence not amounting to criminal negligence

One of the two doctors in charge of the patient

had been in medical practice for forty-six years and had then retired. He was acting as locum tenens for the second doctor from June 2 to 9, the critical week in the patient's illness. The second doctor, having been informed by his colleague that the patient's condition was comfortable, did not visit her on the 10th, as he was not sent for. He saw her on Sunday, June 11, and on other days in that week. On the 17th he was called as the patient was worse. He then decided that she must go to hospital and he communicated with the county medical officer and made the necessary arrangements. Both doctors contended that it was not the usual practice either to send such cases to hospital within twenty-four hours or to call in a specialist. "This was an accidental case," said one of them, "a case in a hundred." "We cannot," said the other, "have a specialist on every abortion." While both of them were aware of the county council's scheme and were in sympathy with the greater attention now being paid by local authorities to welfare in maternity cases, they seemed inclined to dispute the value of the medical opinions on which these schemes are founded. Dr. Grace, on the other hand, was clear that there was a recognised medical practice in these cases, and the coroner (who evidently accepted his view) remarked that the attitude of the two doctors would frustrate the whole scheme.

GRAINS AND SCRUPLES

Under this heading appear week by week the unfettered thoughts of doctors in various occupations. Each contributor is responsible for the section for a month; his name can be seen later in the half-yearly index.

FROM A WOMAN PUBLIC-HEALTH OFFICER

III

It would be interesting to know how many members of our profession bothered to read the exhaustive report on West Indian conditions prepared by the British Medical Association for the recent peripatetic commission. Probably not many, though it was a remarkable document, and the subject is one of grave concern to all of us, now that the relations of Britain to her colonies are an international question. The story is not a pretty one. Curable diseases not cured, preventable diseases not prevented, ancient plagues on the increase, malnutrition rife in a land of natural plenty, housing that would be intolerable for savages, and all this in an Empire of which we are justly proud. Judging from the report and other evidence offered to the commission conditions on the whole seem to be worse than when I toured the islands with a medical colleague nearly twenty years ago. Now, these West Indian islands are as lovely as a dream—lovely as film stars and as diverse in their types of beauty, in race, in religion and in their personal relationships. One might add that they are as sensitive to rivalry; the European enthusiast who always begins by advocating wide schemes of amalgamation has his troubles ahead of him.

* * *

We were fortunate in that the deficiencies of post-war transport marooned us for three weeks in the Panama Canal zone; we were thus enabled to measure West Indian conditions against the standard of the finest hygienic administration in the world. It was amusing to find that the Canal Zone is the doctor's paradise, and the older American officials who had seen the enterprise through from the beginning were quite clear as to the reason. "It was really the doctors who built the canal. The French engineers were as good as ours if not better, but they hadn't a chance. That bit of the old De Lesseps Canal over there cost a life for every yard. Then Dr. Gorgas came along and cleared out the Yellow Jack and malaria, and taught the labourers from the West Indies ('British objects' they call themselves) how to keep alive. Gorgas showed them how to eat so as to increase their work-output, and the canal got built. So do we listen to the doctor's say-so? Yes, Ma'am."

Still, it was a shock to learn, for example, that no one is allowed to remain ill in bed in his own house for more than two days. On the third day the doctor must report the case and the patient is wafted away by ambulance-train to one of the magnificent hospitals at either end of the Zone. No bush or tree grows in the Zone except by permission of the medical officer of health. He is also empowered to inflict and collect fines for breaches of the sanitary regulations and even the local mayor can be fined up to 50 dollars if he gives trouble. I tell you, it would warm the cockles of a "sair hadden doon" medical officer's heart to watch the sort of police-court held every morning in the public-health department, with the M.O.H. acting as magistrate and sanitary inspectors collecting the fines on the spot. Even the ice cream supply had been taken over by the health department and it was issued daily as a government ration. (Socialists may care to note for propaganda purposes that it was the best ice-cream encountered in three continents.)

Walking through the completely fly-less market at Panama with the health officer one came on a banana-skin lying in the central aisle. Can you imagine what would happen if one of H. M. Bateman's admirals found a banana-skin desecrating his quarter-deck? The ensuing scene was just like that. . .

A few weeks later I was escorted through the market of a large West Indian capital town by another health officer; one's feet slithered in the decaying refuse, flies swarmed everywhere. "Now would you like to see where the flies come from?" asked the M.O.H. cheerily. We drove out to a huge dump a mile or so outside the town where flies and rats swarmed like the plagues of Egypt. The town council were going to do something about it next year—I believe it is there still. In another colony we visited a great sugar plantation. Stables for mules, with masses of flies breeding in the neglected yard, could be seen on one side of the manager's house; on the other was a hospital for East Indian immigrants with many cases of enteric in its unscreened wards. Oddly enough the manager himself lay dying of enteric.

We had been sent out especially to investigate the problem of venereal disease, but serious as that was it seemed to us one of the least of the West Indies' troubles. The deficiencies in environmental hygiene, the vast amount of preventable disease such as hookworm, yaws, tuberculosis and (in some islands) malaria, and the huge infantile mortality, seemed much more important. Hookworm is a particu

larly obnoxious scourge to a country One cannot tell what the potentialities of a population really are till it is eliminated I saw in one of the smaller isles a village inhabited by "red shanks," the white descendants of Cromwell's political deportees They were a gentle listless people, with pale blue eyes and skins like badly tanned leather, and it was very tempting to dogmatise about "degenerate stock" But one was told that when cleared of hookworm they become unrecognisable—vigorous and alert in a few months Alas, the medical officers of the Rockefeller anti hookworm campaign have apparently had to leave the islands in despair from lack of coöperation They had told us that the task though difficult was in no way impossible if proper help had been forthcoming

* * *

Leprosy is an affliction so tragic that greater efforts should surely be made to eradicate it Many of the lepers are infected very young and have an appalling life of boredom while waiting for a dreadful end We visited every leper colony in the islands and some of them had not had a visitor for years, the courage and devotion of the officers who were working in loneliness to mitigate their charges' hopeless lot were beyond praise In another colony years later I found that the governor's wife had broken down an ancient taboo, had brought in a committee of ladies to organise games and cinema shows and occupations for the lepers This seems the only way to remove prejudice and to terminate the practice of concealment which is fostering this disease

* * *

One has been hearing a great deal—though not too much—about the housing of the native worker This is a welcome change, for there was a conventional theory in the past that coloured people could live anywhere and on anything, that they revelled in squalor and had no desire for a better standard One noted suspiciously that these views closely resembled the arguments brought out to oppose slum-clearance and rehousing schemes at home The health officers and experienced practitioners one met didn't hold with them Then one day, on a visit to a famous estate, I managed to slip off to the workers' village and have a chat with the people themselves One began with the women and babies, who were friendly as *always* Presently a young man broke off from a group of onlookers and said insolently "Have you come down here to laugh at de black folks living like pigs?" After a word or two of explanation they took me round their disgusting quarters quite willingly and showed me just what they objected to and what they wanted Resentment was freely expressed that the company's officers had rehoused themselves in beautiful screened bungalows and had done nothing for the workers This was no manufactured agitation but the spontaneous expression of simple people up against the fundamental realities of life

In view of the recent riots it is well to recall the freedom from crime (except larceny), the decent behaviour and the kindly patience of the West Indian Why have we made such a mess of a land where every prospect pleases and man is no more vile than usual? Most people know *some* of the answers but no one knows *all* the answers to that query Economic insecurity is one of the more obvious explanations The main industries—sugar, cocoa, bananas—are on the verge of bankruptcy, only oil pays steadily The explanation lies deeper, however, for even during a boom period—and there was great prosperity when I was out there—they did not spend money on health or indeed on any other public purpose (The hospitals—and deplorable they are—are all run by the government) Not one penny of the great fortunes made in the war was expended on any charitable or philanthropic project whatever And the income tax—if any—was only 1*s* in the pound!

More fatal even than poverty was the lack of a communal sense of responsibility for the well-being of the workers This is partly due to racial complexities, and partly to an obsolete political philosophy One met prominent persons who really believed that trade unions are dangerous revolutionary organisations, and that unless corrupted by bolshevik gold coloured folk would be content to sit like Ferdinand the Bull under the cork trees, just smelling the flowers, and never never asking for a share in the higher standards of living that the rest of the world enjoys This is an illusion of the type which has drenched Russia and Spain in blood The Almighty could of course have made such a people but I do not think He ever did

One feels that if it is humanly possible Britain should in the near future take effective action to assist the colonies in clearing up these outstanding arrears of disease and misery One can plead that here the medical officer of health is on the side of the angels—that he stands for social and moral security In the stately words of old Simon (recently recalled by Prof Major Greenwood) "side by side with pestilence there stalks a deadlier presence, blighting the moral existence of a rising population; rendering their hearts hopeless, their acts ruffianly and incestuous and scattering, while society averts her eyes, the retributive seeds of increase for crime, malevolence and pauperism"

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 1, 1939

Notifications.—The following cases of infectious disease were notified during the week. Smallpox, 0, scarlet fever, 1751, diphtheria, 882, enteric fever, 30 (29 "expected"), pneumonia (primary or influenzal), 449, puerperal pyrexia, 162, cerebrospinal fever, 20; acute poliomyelitis, 3, acute polio-encephalitis, 2, encephalitis lethargica, 6, dysentery, 57, ophthalmia neonatorum, 90 No case of cholera, plague or typhus fever was notified during the week

The number of cases in the Infectious Hospitals of the London County Council on July 7 was 2922 which included Scarlet fever, 718 diphtheria, 849 (carriers 11), measles 17 whooping cough, 784, puerperal fever, 19 mothers (plus 8 babies) encephalitis lethargica 306 poliomyelitis 3 At St Margaret's Hospital there were 24 babies (plus 12 mothers) with ophthalmia neonatorum

Deaths.—In 126 great towns, including London, there was no death from smallpox, 1 (0) from enteric fever, 5 (0) from measles, 2 (0) from scarlet fever, 16 (1) from whooping-cough 16 (2) from diphtheria, 21 (6) from diarrhœa and enteritis under two years, and 9 (3) from influenza The figures in parentheses are those for London itself

Huddersfield reported the only death from typhoid Sunderland and Stoke-on Trent each had two deaths from whooping cough Fatal cases of diphtheria were scattered singly over 14 great towns Birmingham reporting 2

The number of stillbirths notified during the week was 237 (corresponding to a rate of 30 per 1000 total births), including 28 in London

LETTERS TO THE EDITOR

CHEMOTHERAPY AND THE WHITE CELLS

SIR,—Although very few are now in doubt as to the immense value of the sulphonamide group of drugs in certain infections, those who are watching the literature dealing with them must be gravely concerned about the increasing number of reports of agranulocytosis associated with their use Once again we are reminded that there must always be danger in the administration of large quantities of a foreign chemical substance—we have to pay a price

Dr Sutherland's report in your issue of May 27 tells the story of the fourth case that has occurred in this hospital during the last two years (three in which the elimination of polymorphs from the blood-stream was complete and one of neutropenia—40 per cent. polymorphs). A fifth case was recently admitted with complete absence of polymorphs (W B C 850) after receiving 40 g. of sulphanilamide in seventeen days before admission. She died within thirty-six hours.

An incomplete survey of the literature shows that during the same period at least twenty-seven cases in adults and three in children have been reported or briefly referred to, making a total of thirty-five up to date From reports reaching me privately I conclude that a larger number of cases have been recognised in this country but not published; and—what is still more disquieting—there can be little doubt that others again have died unrecognised because leucocyte counts were not made. Therein lies the danger. As Dr. Sutherland points out, the clinical picture of agranulocytosis presents nothing characteristic—the so-called agranulocytic angina often does not occur or develops only shortly before death; it was present in only one of our five cases If white-cell counts are not made at short intervals, the patient's rising fever and deteriorating general condition may readily be ascribed to an exacerbation of the septic infection for which he or she is being treated The three cases referred to by Dr Crofton in his letter in your issue of June 24 illustrate well the insidious onset of this condition; he also points the way to the avoidance of the danger.

Very little is yet known about the pathology of agranulocytosis. It has been reported occasionally in association with streptococcus infections apart from any treatment by sulphanilamide or amidopyrine or related drugs, but the recognition of so many cases since the introduction of the sulphonamide group of drugs makes it almost certain that the administration of these drugs has usually been the deciding factor. Whether the presence of the drug itself in the circulating blood, or some derivative of it, is directly responsible, or whether again the condition may be due to a combination of factors, possibly including something unusual in the metabolism of the patient, we do not yet know. Until the condition can be induced in experimental animals these questions will probably remain unanswered.

Meanwhile, a survey of the recorded cases yields some points that are worthy of attention:—

(1) It is clear that agranulocytosis resulting from the sulphonamide group of drugs is a very fatal complication—more than 50 per cent. of the patients having died.

(2) Agranulocytosis may be met with after treatment by any of the sulphonamide group of drugs. Most of the recorded cases have occurred in association with sulphanilamide itself (perhaps because this drug has been more extensively used than any other), but already six cases have been recorded after the administration of M. & B. 693, as well as three cases of neutropenia. So far as I am aware, only one case has occurred when Red Prontosil alone was given.

(3) The relationship of the amount of drug administered and the duration of treatment to the development of agranulocytosis is striking. In twenty-four adult cases reported in sufficient detail the average dose administered was 48 g., and the duration of treatment was twenty days. In only two cases was the total amount less than 30 g (20 g. of M. & B. 693 in one case; 18 g. of sulphanilamide in the other). It is also worth noting that in no less than eleven cases out of nineteen in which the details of treatment are given the fall in the leucocyte count took place during a second or third or fourth course of treatment.

These data seem to point to a fundamentally important conclusion—namely, that there is not much margin between the amount of sulphanilamide which appears to be necessary to control a severe streptococcus infection (20–30 g.) and that which, in some people, involves a serious risk of agranulocytosis (30–60 g) (Comparable figures for M. & B 693 cannot yet be given) If that conclusion is right, it shows, I think, where we have gone wrong in our employment of these valuable new remedies We have continued them too long in cases which have not made a prompt response. Our experience at Queen Charlotte's Hospital has been that, if a patient's temperature chart and general condition do not show unmistakable improvement within the first five or six days of treatment, it is unlikely that there will be any response from further treatment. When hæmolytic streptococcus infections have not responded satisfactorily, it has usually been, in our experience, because the organisms are not sensitive to the drug (as shown by an in-vitro test). Other puerperal infections, except some by staphylococcus and the urinary infections by *B coli*, have almost invariably not responded, and, in my opinion, should not be treated by these drugs.

Since it is not practicable to make frequent white-cell counts in every case treated, I suggest the following procedure as a reasonably safe compromise—at any rate for the treatment of febrile conditions. If a patient's fever is subsiding satisfactorily under treatment and the general condition shows corresponding improvement, there is no need to do white-cell counts for the first six days—and the drug may be continued for a further two or three days without anxiety If, on the other hand, the temperature does not show a prompt response, or there are other disturbing symptoms, such as headache, white-cell counts should be done every second or third day from the beginning of treatment. Similarly, in every case in which more than 25 g. has been given or treatment prolonged for more than ten days, white cell counts should be done at short intervals.

May I add a further note with regard to the treatment of agranulocytosis since varying opinions are being expressed about the value of Pentnucleotide and of transfusion Three of the four patients who developed the condition in this hospital have recovered (the fourth was a case of endocarditis), and the astonishing recovery of Dr. Sutherland's patient when her condition seemed absolutely hopeless has taught us that one need not despair, even if the leucocyte count continues to fall after the drug has been stopped. The intramuscular injection of pentnucleo-

tide (0 35 g twice daily) certainly seemed to induce a definite rise in the leucocyte count *before blood-transfusion* in one of our cases, but we are inclined to think that both measures have proved useful Since we seek especially to provide the patient with normal leucocytes, it seems to me reasonable to use defibrinated rather than citrated blood, taken from donors in whom a leucocytosis has been induced—e g , by intramuscular injection of nucleinic acid (Parke Davis's "Veterinary Nuclein") 2 c cm four or five hours earlier (Colebrook, L , *Proc R Soc Med* 1926, 19, 31) A simple calculation will show that 2 litres of blood containing 12,000 white cells per c mm given (by the drip method) to a patient with 6 litres of blood should raise the polymorph count from 0 to approximately 2400 In some cases the transfusion may need to be repeated.

I am, Sir, yours faithfully,

LEONARD COLEBROOK

THE PROBLEM OF MEDICAL LITERATURE

SIR,—Your correspondents have suggested various remedies for the present chaotic state of the production and distribution of medical literature The production is a special aspect of scientific communication which was vigorously discussed by Sir William Bragg in his presidential address to the Royal Society last autumn I need not discuss here the solutions under consideration As to distribution, Mr Barnard has pointed out the ways in which librarians are already tackling the problem Britain has an unrivalled wealth of medical libraries, but their collections are not coördinated and do not cover the whole field The union list of their periodicals which Mr Barnard is compiling for the Library Association will be an indispensable guide to these collections, and it is to be hoped an incentive to coördinate and complete them.

The scheme of cooperation between certain medical libraries in London, which Mr Barnard also described, has a more immediate purpose May I speak more fully of its aims, and if possible clear up the mis understanding which underlies such criticism as Mr Thornton's, who wrote of the dangers of unofficial coöperation? Coöperation between the libraries of the London School of Hygiene, the Medical Research Council, the Royal College of Surgeons, and University College has been officially approved by the authorities of each institution with the active collaboration of their scientific staffs Our purpose is to begin with this small group of libraries so that our efforts may be practical from the start We hope that other libraries may join us later, including those of societies which serve their own members and not the profession in general

The coöperating librarians will consult one another regularly for the correlation of their activities We mean to attack limited objectives one by one We have begun with the coordination of subscriptions to current periodicals We do not intend to evade duplication where this is required by the scientific workers in each institution, but already in a few months we have cleared up much uneconomic duplication The unwanted periodicals will be discontinued in each library solely to make money available for buying periodicals not yet taken by any of the libraries The working of the scheme depends, as Mr Barnard says, on successful inter library lending But it is essential that it should not be a matter of "librarians persuading their committees," but of close collaboration between librarians and scientific workers

Some of your correspondents have suggested a committee or conference to discuss the problem, is there not need for a wider organisation, a permanent association of medical men and librarians to plan and foster a system of mutual help between all medical libraries? Any schemes for a central library or a central abstracting service must take into account the wealth of medical literature already in the country We who have started this coöperative scheme in London believe that this wealth can be most fully used by correlation of the existing medical libraries, both in collecting the literature and in making it fully accessible through organised service

I am, Sir, yours faithfully,

W R LE FANU, Librarian.

Royal College of Surgeons of England, London, W C 2, July 10

THE NEW ZEALAND POSITION

SIR,—The remarks of your Australasian correspondent on July 1 (p 53) will doubtless call forth a reply in time from New Zealand, but, as one who has just returned from a visit to the Dominion, I feel bound to point out that your readers may get a false impression from what your correspondent writes His contribution is suspiciously like a bit of special pleading for the government and does not give a fair account of what is happening to the profession there

During long negotiations the government rejected the proposals put forward by a unanimous profession The contracts mentioned were for maternity benefit only, the thin end of the wedge The figures given for the doctors' acceptances are correct, but no mention is made of the fact that only a very small minority of the maternity nurses signed their contract

No authentic actuarial report on the social security scheme has been published, although it is alleged that an experienced health insurance actuary was employed. It seems to me that the scheme is top heavy and that the government will be only too glad to blame the doctors if it fails to operate smoothly

I am, Sir, *yours faithfully*,

WM BROWN

Bythorne Galashiels, Selkirkshire, July 8

PROPRIETARY NAMES OR PHARMACOPŒIAL EQUIVALENTS

SIR,—For some time past we have been impressed by the widespread use of proprietary names for certain drugs, particularly in the prescribing of sedatives The following quotation from the recently published "Textbook of Medical Treatment" by Various Authors (Livingstone, 1939) illustrates our contention —

"It is a wise plan to arrange for the patient to have a succession of good nights at the beginning of treatment, by giving a mild hypnotic analgesic (e g *medinal* gr v with aspirin gr x, *luminal* gr iss with aspirin gr x or one of the proprietary preparations such as Lumyrin or Veganin)" (p 731) (Italics ours)

The fact that we are able to quote this example from a book in which great care is taken to give pharmacopœial equivalents wherever possible indicates how well established the habit has become

We feel that in these anxious days this whole question assumes a new urgency in view of the fact that, whether we prefer these proprietary drugs or

not, we may be soon deprived of any possibility of using many of them. In our opinion it would be a valuable service to the profession and to the nation if you could give due prominence to the alternative British or pharmacopœial names for foreign drugs.

We are, Sir, yours faithfully,

T. FERGUSON RODGER,
JOHN D. SUTHERLAND,
SUSANNAH DAVIDSON.

Great Western Road, Glasgow, W 2, July 10

*** For several years we have printed proprietary names with an initial capital letter on their first appearance in any article, and in editorial pronouncements we have preferred to use the pharmacopœial equivalents. We shall increase our efforts to make them more familiar.—ED. L.

PSYCHOTHERAPY BY LAYMEN

SIR,—The published conclusions of the British Medical Association's mental-health committee with regard to the training and recognition of lay psychotherapists were recently considered by the committee of the British branch of the International General Medical Society for Psychotherapy (I.G.M.S.P.), who would like to submit the following comments for consideration

While admitting the present disproportion between patients requiring psychological treatment and those qualified to give it, the solution of this problem by the training of lay psychotherapists is open to the following objections.

1. The proposed lay psychotherapist, unlike other medical ancillaries, will in fact carry out work which is indistinguishable from that undertaken by the medical psychotherapist and consequently must come into direct competition with him.

2. The possibility of relegation of this work to a lay assistant lowers the status of psychotherapy and so of psychological medicine as a whole, with the result that the present endeavours to improve both undergraduate and postgraduate teaching in this subject may be relaxed, to the detriment of medicine as a whole.

3. There are serious practical difficulties in the proposed relationship between the diagnosing physician and the lay therapist which may be fraught with serious danger to the patient.

Psychiatric diagnoses can often only be arrived at in the course of prolonged observation while the patient is undergoing treatment, and it is difficult to see how the lay psychotherapist could be trained in a reasonable space of time to undertake this and at the same time assess the importance of physical factors which so frequently intervene.

4. The important issue at present is to increase the facilities for and adequacy of the training of medical psychologists, since at present there are lamentably few who are really competent to supervise treatment by a lay psychotherapist. The provision of training for the latter may only prove a makeshift policy which will delay the major necessity. Furthermore it seems premature to institute training for the laity when the criteria for medical training for the specialty have not yet been settled

Finally, it is still more important to awaken the public to the importance of adequate prevention and treatment in the mental-health field.

We are, Sir, yours faithfully,

E. B. STRAUSS,
President of the British branch;
H. CRICHTON MILLER,
Vice-president of the Society;
R. HARGREAVES,
Hon. Secretary of the British branch, International General Medical Society for Psychotherapy

July 6

PENSIONS FOR SPINSTERS?

SIR,—As founder and hon. national organiser of the National Spinsters' Pensions Association I would like to make a few comments on your leading article of June 24.

You are quite right in stating that the committee of inquiry did not seem to be able to come to any definite conclusion. Their report has rightly been called a neutral document from which one might read whatever one cared to read, according to one's sympathies or prejudices as the case may be Contrary to your statement that our case failed to survive the cold light thrown upon it by the actuary, we claim that not one of the facts or figures in our "charter" was challenged; the actuaries merely dealt with the case from a different standpoint—in order to complicate it?

I wish also to correct your statement that we deplored our inability to *leave a pension to dependants* We did no such thing, but we do insist that we do not get the same proportionate value for our 5½*d.* contribution as the man receives for his double contribution of 11*d.* A man's contribution of 11d qualifies him for a pension at the age of 65, and also one for his wife on reaching that age. In the event of his death his widow is entitled to a pension of 10*s* (at any age) and his children are eligible for maintenance until school-leaving age For the spinster's contribution of 5½*d.* she can only qualify for a pension for herself at 65 If she dies before reaching 65 nobody belonging to her will receive any benefits; further, if she drops out of insurance before 65—as so many of them do—she loses her pension rights. (All her previous contributions are clear profit to the scheme)

With regard to the "war spinsters," not only our association but all thinking people who have considered the statement of the actuary—that the war did not result in there being a greater number of single women—contend that if by statistics the "war spinsters" can be explained away, then by statistics any other fact can be explained away. There are hundreds of "war spinsters" within our ranks, statistics cannot dispose of them, and you will probably be aware that the press of the country has taken up the cudgels on our behalf with regard to this absurd statement of the actuary.

The report did, however, prove that our grievance with regard to the preferential treatment which is given to the widow is justifiable. It showed that the Government pay a subsidy of 35 per cent. to one section of the widow community, many of whom are young, able-bodied and childless, and 100 per cent. to the pre-act section at 55 years, the age at which the *paying* spinster demands her pension.

With regard to your remark about bath chairs, I should like to ask how is anyone going to subside into a bath-chair on 10*s* a week? I am well aware that at the present time all the nations are looking to the cradles, but surely the wealthiest nation in the world has not yet reached the stage when it must withhold support from its ageing people who have served it so well in the past The women with whom our association is concerned—the ageing working spinsters—have contributed largely to the creation of the vast wealth of this country, which wealth at the present time is enabling us to hold our own amongst the nations of the world. These are the women who replaced the men during the last war, and of whom the war service has taken such a toll of their health.

It is widely known how the spinster has always shown a remarkable spirit of self abnegation in respect of ageing parents and dependant relatives, this spirit has in many cases been responsible for her state of spinsterhood. Even now we are not asking that she be specially compensated for her wealth-creating and domestic services, but that she should have fair consideration along with the rest—that she should receive the same value for her contributions under the national health and pensions acts The committee of inquiry were unable to prove that her grievance was not a genuine one

We are sorry that THE LANCET has entered the ranks of our opponents, but we are happy to be able to state, with authority, that we have many staunch supporters in the medical profession, and in the House of Commons we have Members of Parliament who are supporting us not only as *politicians* but also as medical men

I am, Sir, yours faithfully,

FLORENCE WHITE,
Hon National Organiser, National Spinsters' Pensions Association

PARLIAMENTARY INTELLIGENCE

ON THE FLOOR OF THE HOUSE

By MEDICUS, M P

ON Friday of last week a thinly attended House of Commons listened to a statement by the Minister of Agriculture, Sir Reginald Dorman Smith, on the milk industry Compared with its predecessor, which was withdrawn in February because of opposition from farmers and distributors, the Government's present bill may be described as one having the milk left out and the subsidy left in But it is unfortunately worse than that The original bill provided for the setting up of a milk commission "to keep generally under review matters relating to the milk industry" and to advise and assist the Ministers It created a constitution and a living brain for the milk industry, made provision for pasteurisation, and allowed for expenditure on research and education But all this has gone

The Minister began with an excuse when he said that since the withdrawal of the earlier bill it was "not now possible to introduce this session any fresh proposals which can even purport to be called comprehensive" Yet, as he said, the industry is one of outstanding importance More than 150,000 farmers are engaged in dairy-farming and the annual output of milk and milk products is valued at more than £60,000,000, or about a quarter of the total value of agricultural output The debate showed clearly that the purpose of this bill is to carry over the present unsatisfactory arrangements for milk-supply for a further period, but no new proposals are made and the vital problems of safe milk and of cheap milk are left in the air Clause 2 gives powers to the Minister to make grants for cheap milk for school children, expectant and nursing mothers and children under five, but there is considerable doubt as to how much milk will reach those for whom it is intended Not a penny of the £250,000 voted last year for this purpose has yet been spent, and members not unnaturally asked what is the use of voting money for benevolent sounding schemes if they are not put into operation Another feature of the bill—one becoming common in connexion with subsidies—is that payments are to be made retrospectively as from Oct 1, 1938, but as Dr Haden Guest remarked, milk cannot be given retrospectively to the expectant and nursing mothers and children under five whom Parliament in July, 1938, intended to benefit

The bombshell of the debate was left to the end when the Under Secretary for Scotland, Mr Wedderburn, in his reply left out all reference to future Government policy on pasteurisation In reply to a question by Mr A V Alexander he announced that the Government would do nothing, but recommended that local authorities—Glasgow was mentioned—should promote their own bills to secure powers in their own areas The Government last year asked local authorities *not* to promote bills of their *own* Now they have reversed that policy and ask them to do so if they wish Sir Francis Fremantle was not alone in feeling disturbed at this proposal to "pass the buck" to the local authorities The question that was in most members' minds was, "ought there not to be some definite protection for the community against disease?" And so the debate ended on a note which, as one agricultural member emphasises from time to time, was "thoroughly unsatisfactory"

FROM THE PRESS GALLERY

Milk Policy

IN the House of Commons on July 7 Sir R DORMAN-SMITH, Minister of Agriculture, moved the second reading of the Milk Industry (No 2) Bill Since the former bill was withdrawn it had been necessary, he said, to re-examine the whole problem of milk policy It was not now possible to introduce *proposals* which could even purport to be called comprehensive Certainly the fitness and health of the nation would be improved by a greater consumption of milk The Advisory Committee on Nutrition had recommended a pint a day as the desirable ration to aim at, whereas at present the average was less than half a pint But the nation was becoming more milk-conscious, he paid a tribute to what the teachers had done in connection with the *milk-in-schools* scheme As a result the number of children taking milk in schools in England and Wales had gone up from 900,000 to well over 3,000,000 and the number was still increasing In the last milk contract year the increase in the consumption of liquid milk was estimated at about 35,000,000 gallons net in England and Wales As a result of the scheme for the *encouragement of the* production of clean milk at the present time over 40 per cent of the total milk sales were now of at least "accredited" standard Government assistance had also been directed towards the eradication of tuberculosis in cattle

The existing milk legislation was due to expire on Sept 30 next and the purpose of the present bill was to carry on to the end of September, 1940, the activities which had already been started The *measure had three main objects* The first was the encouragement of quality-milk production by the provision of Exchequer *contributions towards* the cost of premiums paid on *quality milks by milk-marketing boards* The second was to provide Exchequer assistance for the milk *in-schools scheme* and for the supply of milk at reduced prices to mothers and young children The third was to put a *bottom into* the market for milk sold for manufacture into butter and cheese The estimated cost to the Exchequer of these proposals was for the current milk year about £1,000,000 and for the next milk year about £2,200,000, in addition to the expenditure (£300,000 and £500,000) under the Agriculture Act in respect of milk from attested herds.

It was the intention to arrange for the supply of milk at reduced prices to local authorities so that they might undertake extensions of their existing schemes for the supply of milk either free or at reduced prices to nursing and expectant mothers and children under five. Already a scheme along these lines had been submitted by the main Scottish milk-marketing board for its area and had been approved. A similar scheme was now under consideration for England. In view of the increased consumption of milk in schools—and he desired to go on increasing that—and the proposed maternity-and-child-welfare cheap-milk schemes the bill did not provide for any overriding limit to the annual grants The Exchequer grant for the coming year would be about £1,000,000, as compared with £500,000 a year hitherto, and about £800,000 for this year.

Mr. T. WILLIAMS, on behalf of the Labour Party, expressed approval of the subsidies for quality milk and for cheap milk-supplies for children and nursing and expectant mothers. They also entirely agreed with the continuance of the milk-in-schools scheme, for with milk at its present price it was impossible for millions of families to purchase the milk they required to keep healthy. But in view of the fact that 40 per cent. of herds reacted to the tuberculin test something more needed to be done. The government had set up a national veterinary service, but there were only 22 veterinary surgeons for the whole of the country, and he urged a much bolder programme of disease eradication and more research; but above all they needed better and cleaner farm buildings.

Mr. W. ROBERTS said the government had run away from the much bigger problem they might have tackled.

Dr HADEN GUEST said that on health grounds nothing could take the place of milk; the present consumption was definitely below what it ought to be, especially among the poorest classes of the population. Under the Milk (Extension and Amendment) Act, 1938, £250,000 was set aside for the supply of milk to nursing mothers and children under five, but up to March 30 of this year none of it had been spent because the Minister had not been able to come to an agreement with the producers and distributors. Payments for milk were under the present bill made retrospective to 1938, but milk could not be given restrospectively to nursing mothers or children under five. He thought the Government were paltering with this question. The farmer got a very low price for his milk while the distributor got a very high price. The farmer should get a better price and the consumer should get his milk at a lower price. At present we had a policy of restricted production and restricted consumption and prices here were higher than in any European country, and higher than in many parts of America. He realised the difficulties of the Government, but it was surely time to put the organisation of the milk industry on an economical footing. The important thing was nutrition and health, and putting a child's needs at a pint a day at least a quarter of the children in the country were getting only one-fifth of the milk they needed. One generation of scientific nutrition and farming policy for the nation would transform the generation on which they were acting.

After further debate the bill was read a second time.

Later, on a money resolution, Dr. HADEN GUEST urged that there ought to be a guarantee that the milk that was to be sold was of a sufficiently high quality not to cause disease. The amount of tuberculous milk sold was a menace to the health of the community.

Sir R. DORMAN-SMITH said the Government wanted to encourage the improvement of milk They were getting on with the eradication of tuberculosis It was not everybody's opinion that pasteurisation was either necessary or desirable. Consumers if they desired pasteurised milk should be able to buy it. It was open for any local authority to present a bill.

Mr. ALEXANDER said he was wholly disappointed with the method of the Government in announcing their policy in this matter. They now found that the agricultural side of the Government at any rate was taking the side of those opposed to pasteurisation and leaving it to the initiative of local authorities to promote legislation. That was a retrograde step.

Brigadier-General BROWN said it was better policy to remove the disease from the herds than to take it out of the milk by machinery.

Sir FRANCIS FREMANTLE said that medical men had been careful to recognise the difficulties of the Government. Agriculturists should realise when they were calling for publicity in order to get the industry back to prosperity that their chief agents were medical men. The medical profession were practically unanimous that milk could be rendered safe. He hoped it would not be left to each local authority to introduce safeguards as to pasteurisation.

Sir R. DORMAN-SMITH said the whole question of milk policy was under consideration with a view to the introduction of legislation at a later date He could not say what the policy about pasteurisation would be.

Scottish Health Services

In introducing the vote for the Department of Health for Scotland in the House of Commons, Colonel COLVILLE, secretary of state for Scotland, gave an account (reported last week) of the contribution the department had made and was making to the health and well-being of the people.

Mr. T. JOHNSTON, speaking for the Labour Party, admitted that great improvements had been made in the physical condition of the people, but urged that the figures for Scotland were disquieting when compared with those for England and Wales They showed 417,000 cases of sickness and incapacity in Scotland in the course of the year and 31,000 of the insured population were out of work for a whole year because of sickness. There must, he said, be a tremendous amount of avoidable sickness and suffering among old-age pensioners.

Sir ARCHIBALD SINCLAIR, for the Liberal Party, agreed that there was much leeway to make up. Infantile mortality in Scotland was still 70 per 1000 as compared with 53 in England and Wales, and the other death-rates still compared unfavourably with those of England. He was glad the estimate for the Highlands and Islands medical service was being raised by £10,000, but that was not enough. One of the worst aspects of the health of school-children in Scotland was the condition of their teeth. Some 56 per cent of the school-children had from one to four teeth decayed Bad nutrition and bad housing were also causes of ill health which needed more attention.

Mrs. HARDIE pleaded for the establishment of clinics for rheumatism.

Mr. HENDERSON STEWART said that it was baffling to him to find that Scotland lagged behind in the race for health and better housing. He could only explain it by assuming that the Secretary of State was so overburdened that he had not the time necessary to think of the big problem of Scotland.

UNDER-SECRETARY'S REPLY

Mr. WEDDERBURN replying to points raised said that properly coordinated plans existed for the organisation of a casualty-hospital service in Scotland in the event of war. The Minister of Health and the Secretary of State for Scotland proposed, at a very early date, to lay before Parliament a white-paper which would give a comprehensive statement of the arrangements made in Scotland as well as in England. The Scottish Secretary would also, at the beginning of next week, issue to all hospitals in Scotland which would take an integral part in the emergency hospital service a statement showing the particular rôle they would be expected to play, and which would also state the approximate numbers of beds which they would be expected to set free for

casualties, the ways in which it was contemplated that these beds would be freed, the probable number of patients to be sent home and the number to be transferred to the institutions to which patients would be transferred from the hospitals With regard to the Highlands and Islands, the Secretary of State had never felt justified in asking for the annual sum proposed in the report on the Health Services for last year, but increases had been obtained for a fairly large number of small objects, and the amount of grant payable this year showed an increase of £10,000 on the corresponding figure for last year, having risen from £90,000 to £100,000. With regard to dental services, the department's medical officer was at present engaged in making a survey of the school dental conditions throughout the whole of Scotland, with a view to making recommendations for the improvement of these services

QUESTION TIME

JULY 6–12

Cheap Milk in Scotland

Mr MATHERS asked the Secretary of State for Scotland how much of the Exchequer subsidy voted under the Milk (Extension and Amendment) Act, 1938, was being used to help maternity and child welfare authorities to start cheap milk schemes, and the price charged to the local authorities for the milk, how many authorities had inaugurated such schemes, and their names, how many expectant and nursing mothers were receiving milk free and for payment, and the price in the latter case, and how much milk was normally given daily in each case, and for what period —Mr COLVILLE replied A sum of £16,050 has been provided in the estimates of the Department of Agriculture for Scotland for the current year in connexion with the sale of liquid milk at a reduced price to local authorities in Scotland for the purpose of their maternity and child welfare arrangements A scheme by the Scottish milk marketing board was approved on Feb 6, 1939 Local authorities within the board's area can obtain supplies at 8*d* per gallon for ordinary milk or 9½*d* per gallon for tuberculin tested milk, plus the cost of distribution Arrangements by Glasgow corporation under the scheme have been approved and proposals by six other authorities (the county councils of Dunbarton, Selkirk and Stirling and the town councils of Dumbarton, Dunfermline and Stirling) have been received and are under consideration The arrangements provide that, normally, one pint of milk will be supplied daily, either free or at a price not exceeding 2*d* to expectant or nursing mothers and to children under five years of age where the family income is within a scale adopted by the local authority and approved for the purposes of the scheme So long as the applicant continues to be qualified there will be no limit to the period during which a supply of one pint daily may be given The Glasgow arrangements came into operation only on July 1 and information as to the number of participants is not yet available

Fresh Milk in Schools

Mr DUNN asked the parliamentary secretary to the Board of Education how many schools, elementary or secondary, there were where fresh milk was not available for the children in England and Wales, and if he would say what was the reason for this and what he proposed to do to correct it —Mr KENNETH LINDSAY replied The number of public elementary school departments in England and Wales in which it is known that milk was not available in any form on March 31 last was 1574 out of a total of over 29,000 There were also certain other departments, the number of which it has not been possible to ascertain in the short time available, in which only dried milk was provided On the same date there were 132 grant-earning secondary schools in which no liquid milk was available The principal reasons for the failure to provide liquid milk are the difficulty of finding a supplier for small and remote rural schools, the inability of the medical officer of health to approve as safe the only milk available, and in a small minority of cases the unwillingness of the teachers to operate the scheme An analysis of all these cases is being made with a view to ascertaining the reason in each case

Mr. DUNN Is this due in any degree to the operations of the Milk Marketing Board?— Mr LINDSAY I do not think so In so far as the small rural schools are concerned we are now engaged with the Milk Marketing Board in trying to overcome this difficulty If I explained the matter at greater length I could show that there are many other factors which enter into the question

Milk for Mothers

Mr BROOKE asked the Minister of Agriculture what percentages of the persons eligible were participating in each of the existing special area schemes for the supply of milk at a reduced price to nursing and expectant mothers and children under school age, and whether the price per pint was the same in each case —Sir WALTER WOMERSLEY replied My right hon. friend is informed by the Milk Marketing Board that, of the persons eligible to participate in the experimental schemes for the supply of milk at reduced prices to nursing and expectant mothers and children in the special areas, the proportions that have availed themselves of the facilities are 60 per cent in Jarrow, 61 per cent in Rhondda and Walker-on Tyne, and 65 per cent in Whitehaven The milk is supplied at 2*d* a pint, but in Whitehaven a special grant is made from the funds of the Whitehaven Council of Social Service and the Cumberland Friends' Unemployment Committee to enable certain applicants to be supplied with the milk at 1½*d* a pint

Maternity Hospital Accommodation

Mr GORDON MACDONALD asked the Minister of Health what hospital accommodation for maternity cases existed in the Lancashire county council area, giving separate figures for the Wigan county area, whether he was satisfied that such provision was adequate to meet requirements, and, if not, what action he proposed to take to increase such accommodation to the necessary extent — Mr ELLIOT replied Maternity accommodation in the county council's area is available at forty-six voluntary and municipal institutions This provision appears to be generally adequate, but further accommodation is desirable in some particular districts Five extension schemes are already contemplated In the Wigan area, where seven beds are available at Billinge Infirmary, the need for extension is realised and is under joint consideration by the county and county borough councils I am keeping the position under review

London Maternity Services

Mr DUNCAN asked (1) whether he was now prepared to give an emergency grant to the London voluntary maternity hospitals to enable them to tide over the difficulties which had arisen as a result of the passing of the Midwives Act, and in consequence of the new rules of the Central Midwives Board, and (2) if he was now in a position to give a reply to the points raised by a deputation representing the London Maternity Services Joint Committee, which interviewed him on April 19 last —Mr ELLIOT replied The question of grants to training institutions is receiving consideration in connexion with the recommendations of the Interdepartmental Committee on Nursing Services, but I am not yet in a position to make a statement

Foster Mothers

Dr SUMMERSKILL asked whether he was aware that women who were totally unfitted, either from advanced age, ill health, or lack of morals, were able to take foster children provided notice was given to a local authority, and whether he proposed to take any action in the matter — Mr ELLIOT replied I would draw the hon member's attention to section 212 of the Public Health Act, 1936, under which the welfare authority have power to apply to a court of summary jurisdiction for an order to be made for the removal to a place of safety of a foster child [illegible] to be received by a person who, for such reasons as are stated in the question, is unfit to have the care of the child The notice which under the act is required to be given to the welfare authority before a foster child is received for reward should afford the welfare authority

opportunity for action to prevent the reception of foster children by unsuitable women.

Black-listed Elementary Schools

Mr. DUNN asked the parliamentary secretary to the Board of Education how many elementary schools were still on the black list, and how many were provided or non-provided schools.—Mr. LINDSAY replied: The number of public elementary schools still on the board's list of schools with defective premises is 797 of which 225 are provided schools and 572 non-provided schools.

Replying to a further question by Mr. Dunn, Mr. LINDSAY said that a great variety of steps was being taken to correct the position. The main reason for the existence of defective schools at present was the failure to complete the reorganisation, and the only answer to that was to press on with reorganisation. In the case of schools which could be slightly altered, where reorganisation would not affect the problem, the answer was to do away with the obvious difficulties, and that work was being proceeded with.

Medical Education in West Africa

Mr. SORENSEN asked the Secretary of State for the Colonies whether, with a view to the more rapid development of an African medical service, he would make an inquiry into the possibility of creating a medical school in West Africa.—Mr. MALCOLM MACDONALD replied: A school of medicine has been established in Nigeria for a number of years and is making good progress. The whole question of the future development of higher education, including medical education, in West Africa is to be discussed at the conference of West African governors which is to be held in August.

OBITUARY

HENRY HAVELOCK ELLIS

L.S.A., F.R.C.P.

THE nineteenth century is often regarded as an age of unquestioning and self-satisfied complacency. This is not the whole truth, but it accounts for the battles that had to be fought by those original spirits who challenged the confident opinions of the majority. Among the foremost of these disturbers of tradition was Henry Havelock Ellis, who died last Saturday in London at the age of 80.

[Lafayette

Born a few months before the publication of the "Origin of Species," Havelock Ellis grew up in surroundings where sex was regarded as something shameful and *apart from* ordinary life. Its mention was scarcely permitted, and as the obverse *to this reticence* there existed an underworld which Havelock Ellis himself described in his own private diary at the age of 15, after an appreciation of the artistic merits of the statue of the nude Lesbia at Milan:

"But it is the form and the anatomy which principally struck me for their truth and naturalness. I will not specify instances of this because in our present fastidious and decorous age it would be considered a most indecent breach of propriety. Why so, I know not; perhaps I might be told that it would corrupt youth. Though how that can be I know not when it is that same youth who gloats and revels in that which in his hands is transformed into filthiness. Oh! the vistas of disgusting filthiness in a schoolboy's mind which is ever creeping out of his mouth; which he scribbles everywhere, which he must commit to paper, which he must turn into filthy doggerel."*

It is clear that at that early age Havelock Ellis already had that impulse to examine and challenge accepted beliefs which dooms its owner to a struggle against one of our strongest social forces.

A few words about his upbringing may illustrate, if they do not explain, this habit of mind. Ellis came of East Anglian stock. The son of a seaman he spent his youth largely at sea, crossing the Pacific. His education was sporadic and discontinuous and his home life, although affectionate and intimate, was lived in circumstances which enabled him afterwards to say that absence makes conjugal hearts grow fonder. At the age of 16 he found himself in New South Wales teaching in remote schools, writing poetry, reading Shelley and James Hinton, and becoming convinced of the basic identity of science and mysticism which remained his creed. The inner story of these days remains to be revealed, but he might have become another Edward Carpenter had he not made up his mind that a study of medicine was essential to him in clearing up the problems of sex. After four years he returned to London and studied at St Thomas's where he qualified in 1889 at the age of 30. He practised medicine only for a few months and two years later he met Edith Mary Lees who shared his work for 25 years and was herself an essayist and novelist. Even in student days his output of literary work was extensive and varied; he then edited the Mermaid series of "Old Dramatists" and planned the "Contemporary Science Series" which ran usefully until 1914. In the year he qualified appeared "The New Spirit," the first serious challenge to complacency. It was almost universally condemned by reviewers and the reaction was a foretaste of the storm which burst in 1898 over the first volume of "Studies in the Psychology of Sex." One Bedborough, who had sold a few copies of the book, appeared at the Central Criminal Court; by pleading guilty he escaped punishment himself and prevented the presentation of a defence against the indictment which ran thus:

"a certain lewd, wicked, bawdy, scandalous, and obscene libel, in the form of a book entitled 'Studies in the Psychology of Sex: Vol I. Sexual Inversion, by Havelock Ellis,' in which said book are contained among other things, divers wicked, lewd, impure, scandalous and obscene libels, and matters, which said book is, pursuant to the provisions in that behalf, of the Law of Libel Amendment Act, 1888, deposited with this indictment, . . ."

This description of the book expressed the spirit of the times and provides us with a measure of our change of outlook when we compare it with the respect now shown to the memory of Havelock Ellis. Perhaps we are too close to it to consider

* Quoted from Houston Peterson's Havelock Ellis, Philosopher of Love, London, 1928, p. 28

impartially the advantages and disadvantages of our altered outlook Of young people today of both sexes many can discuss and face frankly the problems and difficulties that must in any civilised community arise in connexion with the instinct of sex, which is at the same time powerful and in need of reasoned control The picture that the young Havelock Ellis drew of the filthiness in the school boy's mind is, we may hope, no longer so true There is, we know, more open laxity in sex behaviour than there was 30 years ago, though the influence of the last war had its effect in producing that Perhaps we owe something to Havelock Ellis for our modern courage in openly attacking the incidence of venereal disease He has taught us that the sexual perversions can now be approached, by some of us at least, as problems to be understood and not as examples of wilful depravity, homosexuality is recognised as a condition which, like normal sexuality, may occur in the best and worst of mankind and should be handled in the light of that knowledge

Havelock Ellis himself was shy and retiring he never appeared in public, never lectured, and, strange to say, rarely engaged in controversy except so far as he ably defended his views when presenting them in the written word. The example he gave of the calm pursuit of unpopular truth stands out in a world where the power of reason is becoming more and more stultified by appeals to the emotions of the herd. These qualities could not fail to impress

"In some half dozen conversations held in the course of the last fifteen years," writes C P B, "two of Havelock Ellis's characteristics impressed themselves upon me The first was his generosity to writers on subjects within his special field Since the war there has been a spate of books on the sexual question The bulk of them contained little that was new, they consisted, for the most part, of second hand versions of Ellis's ideas presented with little of his literary distinction and none of his philosophical detachment Yet to the authors of these books he gave nothing but sympathy and encouragement, if criticisms were offered, they were couched in the politest of language It was agreeable to find a great pioneer so completely devoid of petty jealousies The second was his uncompromising refusal to allow himself to be honised Many were the organisations which sought to honour him, their invitations were always met with a gentle yet firm refusal

"The range of Havelock Ellis's culture, though prodigious, is never oppressive, his writings bear the imprint of an acute yet meditative intelligence His mind was delicately attuned to the rhythm and beauty of words, and he combined a quick sympathy for human beings with a philosophical detachment His integrity and courage—a quality much called for by the hostility which his early writings provoked—sprang from his essential generosity, and from the mystical cast of his mind was derived his indifference to the outward marks of human esteem, his fundamental modesty and humility"

SYDNEY BACKHOUSE HULKE

FRCS

THE death of Dr Hulke on June 10 at the age of 68 has removed a popular figure in the medical life of East Kent He was the tenth link in a chain of doctors whose name is closely associated with Deal, where the Hulke family has practised since it was driven from the Low Countries by the Duke of Alva He was in partnership with his brother and his nephew, both of whom predeceased him Sydney Hulke was naturally a Middlesex man and following his famous uncle, John Whitaker Hulke, he took an early interest in the military side of surgery and after a period as surgical registrar he served in the South African war From 1914 to 1918 he worked indefatigably in three hospitals at Deal and Walmer "Hulke," writes FRCS, "fulfilled one's ideal of the best type of British practitioners Nature had gifted him with a fine physique, courage and sympathy, and these were used devotedly in the service of those who sought his professional aid. His temper could not be ruffled —he was never known to be discourteous, and the affection and esteem of all classes was shown by the enormous gathering of rich and poor at his graveside The Hulke tradition is still handed on his married daughter, Muriel Brander, is a fellow of the college"

DAVID MACMILLAN

M D EDIN

A YEAR after his retirement Dr Macmillan died on July 6 at Tunbridge Wells He was a native of Kirkcudbrightshire, being born in 1867 at Chapel and educated at Ewart High School, Newton Stewart, in the neighbouring county of Wigtown Thence he proceeded to Edinburgh University where after taking a degree in arts he graduated in medicine in 1891 In 1897, after a short period of assistantship in Farnworth, Lancashire, he went to Prestwich, Manchester, to join the late Dr Leslie Jones in practice and he remained there for the rest of his working life One who knew him intimately for many of these years writes of the way in which he endeared himself to all with whom he came in contact, and of his loyalty as a colleague "He was a shrewd and kindly counsellor, indefatigable in his efforts to help, always activated by the highest traditions and ever scornful and intolerant of anything that, as we say in Lancashire, was not 'jannock' In his busy life he had little time to cultivate hobbies, but when opportunity offered was very fond of a game of golf or bridge, both of which practices he told me he hoped to indulge in his retirement, so well deserved"

Dr Macmillan leaves a widow, two sons and two daughters

FOOTWEAR AND FITNESS —At a meeting of the National Fitness Council for England and Wales, held in London on July 10, Lord Dawson said that the medical committee of which he is chairman is inquiring into the manufacture of suitable footwear for all classes of the community Sir Kaye Le Fleming announced that a publication is to be issued giving simple rules for the acquisition and maintenance of personal health

THE DIXON MEMORIAL HALL, DUBLIN —The hall erected in Trinity College in memory of the late Andrew Francis Dixon, professor of anatomy and chirurgery in the University of Dublin was publicly opened by Dr W E Thrift, provost of the college, on July 3, in the presence of a large number of friends and former pupils of the late Prof Dixon The hall, which was built from the designs and under the supervision of Mr F G Hicks architect, will be used for meetings and examinations in connexion with the school of physic Dr T G Moorhead regius professor of physic, gave a brief address in commemoration of Dixon's work and personality, and appreciations were added by Prof J K Jamieson, Dixon's successor in the chair of anatomy, and by the provost The funds for building the hall were got by public subscriptions amounting to some £2300 with the addition of a larger amount contributed by the Board of Trinity College

MEDICAL NEWS

University of Cambridge

Dr. A. M Jones and Dr R E Kenny have been elected to Elmore medical research studentships

The title of the degrees of M B , B.Chir. has been conferred on Gwendolen M. Allen-Williams (Newnham).

University of London

Prof Frank Horton, F.R.S , professor of physics in the university, at Royal Holloway College, and a member of the senate since 1925, has been elected vice-chancellor for the year 1939–40 Lord Dawson, who has hitherto been a representative of the faculty of medicine on the senate, has been appointed as a coöpted member in place of the late Sir Frank Dyson.

Mr Harry Stobie, M.R C S , has been appointed to the university chair of dental surgery and pathology tenable at the Royal Dental Hospital of London school of dental surgery.

Mr Stobie, who is 56, studied at the Royal Dental Hospital and at St Thomas's Hospital He qualified L D S in 1910 and for some time held the post of clinical assistant in the dental department at St Thomas's Hospital After taking his M.R.C S. in 1911 he returned to the Royal Dental Hospital as demonstrator in operative dental surgery and tutor in dental anatomy and dental surgery. During the war he served with the R.A M C as officer in charge of division V and surgeon-specialist at the Croydon War Hospital for Injuries of Jaws. In 1915 he became hon. assistant dental surgeon at the Royal Dental Hospital and in 1930 he was appointed to his present part-time posts of hon dental surgeon, dean and director of teaching, and lecturer in dental surgery and pathology at the hospital. From 1932 to 1936 he also held the post of postgraduate instructor in oral surgery at the hospital He is a member of the board of examiners in dental surgery of the Royal College of Surgeons of England and has also examined for the universities of Bristol and Birmingham In 1935 Mr Stobie attended the International Stomatological Congress at Bologna as representative of the Government, and he recently went at the invitation of the Egyptian government to inspect and report on the dental school at Cairo

At recent examinations the following candidates were successful :—

D P H

T. K Abbott (not eligible to receive the diploma until December, 1939), Rosetta C Barker, Lily Bennett, Margaret Brodigan, H B C Carter-Locke, John Clark, C S Davies, D O. Dickie, Jean Duncan Whyte, R. W Elliott, C N Faith, Margaret A B Fleming, May E M Fleming, J F Houlihan, E. C H Huddy, J H Lawrence, H A Leggett, V. N Leyshon, F. D M Livingstone, Jean J Macdonald, J. P. McGladdery, R W. Markham, Isobel M. S Marshall, T. G Martin, E L M. Millar, Anil Mukerji, Dorothea M Norman-Jones, M. N Pal, Peter Pan, M M. Sircar, G R Taylor, R C Wofinden, Grace E. Woods, and Rowena Woolf

DIPLOMA IN BACTERIOLOGY

H. L Carruthers, W. J Godden, D F Gray, G. J. G King, Ian MacKay, C D Parker, *M T. Parker, Y. S Rao, Marion Ross, and L B E Seneviratne

* With distinction.

University of Aberdeen

On July 6 the honorary degree of LL D was conferred on Mr. Cyril Burt, D Sc , professor of psychology in the University of London, and Dr. Alexander Low, professor of anatomy in the university from 1925 to 1938 The following degrees and diplomas were also conferred :—

M D—*J D MacLennan, †A. B Christie, †A. M. Ramsay, J. C Niven (in absentia), and R. W H Welsh

* Awarded highest honours for thesis
† Awarded commendation for thesis

M.B , Ch B—Robert Semple (with first-class honours); Alison B Cruickshank, J. I Rice, R. L Richards, and G S. Riddell (with second-class honours), James Abernethy, L H Allan, Jessie E C Baird, J E A Bartlet, K M Bell, C A Brown, P L Brunnen, W N. Calder, I W Caldwell, W D Catto, George Cormack, D A Craib, Phyllis E. Davidson, Stewart Duff, John Duguid, Jean A Ferguson, Marian M. Fergusson Alice D Findlay, H. R Findlay, R J A Fraser, Rose M. Fraser, L D. M. Gavin, Helen W Geddes, S M Gill, J. S Hamilton, N G C. Hendry, J A. Houston Alexander Hunter, A S Jessamine, Charles Low, Douglas McBain, A. D McGill, J K. Mackay, I A R Mackenzie, Margaret R McKenzie, Malcolm MacLeod, Anne M S Macrae, N. H Mackworth, R G Main, Eric Milne, W S. Milne, John Morrison, C. F. Murison, Janet B Patterson, I D Pennie, J. W Rae, J B Raffan, Mary H. Reid, D H. Rhind, John Scorgie, L T Shennan, G M. C Smith, Helen A Smith, D L Stewart, J. C Taylor, Elizabeth M. F. Tolmie, Sheena M Tosh, Jean C Twort, and P. H R Williams

D.P H—Ann L Shennan (with credit), David Barclay, C E Gorrod, J. J. T. Morrison, J. B. Petrie, G L Ritchie, C. J. Silver, and J. M. Thomson.

Royal College of Surgeons of England

Election to the council—On July 6 three fellows were elected into the council to fill the vacancies caused by the retirement of Prof G E Gask and Sir James Walton and by the death of Prof Graham Simpson. The result of the poll was as follows :—

	Votes
Sir JAMES WALTON (London)	585
CECIL AUGUSTUS JOLL (Royal Free)	518
ROBERT JOSEPH WILLAN (Newcastle)	448
Robert John McNeill Love (Royal Northern)	414
Reginald Martin Vick (St Bart's)	351
Robert Davies-Colley (Guy's)	342
Vincent Zachary Cope (St Mary's)	275
Lennox Ross Broster (Charing Cross)	240
Ralph St Leger Brockman (Sheffield)	198
Sir Lancelot Barrington-Ward (Great Ormond Street)	195
James Ernest Helme Roberts (St Bart's)	191
John Bowman Hunter (King's College Hospital)	165
Julian Taylor (University College Hospital)	164
William Hugh Cowie Romanis (St Thomas's)	156

In all 1669 fellows voted , in addition 17 votes were found to be invalid, and 2 votes arrived too late. Sir James Walton, Mr. Joll and Mr. Willan are all elected for the full period of eight years

University of Manchester

At recent examinations the following candidates were successful :—

M D

Simon Almond, C G Eastwood (with commendation), Evelyn M. Holmes, A. E Martin (gold medal), C S Parker, H T. Simmons, and Colin Starkie

FINAL EXAMINATION FOR M B , CH B

Part II—A D. Leigh and M. D. Milne (with first-class honours), Mary Fleure and A. F. Williams (with second-class honours), G T Ashley, T. G Barlow, Irene M Bower, T M Brand, Frances M Bullough, W. W Burnett, T. E A. Carr, G. R. Crawshaw, Olive I Elkin, R T. Grime, Joan Halstead, Cyril Hamwee, C P Heywood, Hannah Horton, W L R Kenyon, Joseph Latham, Joyce Leach, R A. Martin, A P Massie, Asa Mills, M. J. Parsonage, J. R Platt, T H Redfern, Edward Ridehalgh, Benjamin Roditi, E. S Rogers, M S Rowley, L D Rutter, J. E. Schofield, Barbara M Statham, F. W. Taylor, M R. Tomlinson, G. K. Tutton, and R. M Winston

Part I—Arnold Ashworth, J. H. R Barker, F R Brebner-Smith, Thomas Brittain, Gerald Caplan, Rachel Claiman, Hilary J Crewe, J G Ferguson, E S Frazer, R J Gampell, James Gregory, Hilda R Harris, Harold Hassall, Stanley Haythornthwaite, Irene E Howorth, Margaret Jacques, Oscar Janus, P W. Kippax, J T A. Lloyd, J L. MacLean, William Mellor, Elsie L Mettam, Catherine E D. Nash, Christopher Parish, K C Prausnitz, T F. Redman, Frank Robinson, Margaret H Roscoe, J C Seddon, G. K Spruell, J K Steward, T. A. Taylor, Edith M Thorp, A L Tulk, Ena M. Walmsley, and Joyce Worthington

D P H.

Part II,—Randle Bennett, Caroline J Chalmers, William Fielding, G. M. Fleming, D. M MacKechnie, H. D. B. North, R M Shaw, G R Walker, and A B White

Part I—S G. Abelson, D H. Anderson, H S Bagshaw, Caroline J Chalmers, J R Davidson, William Fielding, G. M. Fleming, Neil Maclean, H N Osborne, Morris Pivawer, R. M Shaw, Fred Stratton, and A B White

University of Dublin

On June 28 the following degrees were conferred :—

M.D.—J E Gillespie

M B., B Ch , B A O—R S W. Baker, H S Boyce, W. F. Carpenter, A C Corbett, J K Craig, Edward Cullen, Matthew Daly, Jack Freedman, S M Freedman, Leslie Fridjohn, Arthur Graham, J P Gore-Grimes, Sylvia M Hall, G. H Henry, Myer Herman, E G Hobart, D W McCarthy, Noel McSharry, L. E. Morris, C B Robinson, C H Rutherford, G S Sheill, W. B Wolphy, J D Whiteside, Frank de Burgh Whyte, V. T. Williams, and F L Willington

B Dent Sc—C J Dugdale and R D Jones.

At recent examinations at the school of physic, Trinity College, the following candidates were successful :—

M D

Marjorie R E Boyd, J E Gillespie, H B Sutton, and H B Wright

FINAL EXAMINATION FOR M B , B CH , AND B A O

Therapeutics and pathology—Maude F P Bigger (first-class honours) G S Prince, W G D Caldwell, and G B Gibson (second-class honours), Kathleen M J Morphy, Helen S Watson, B W Wyllie, J R Hassard, D W Montgomery, C E Williams Ivy K Bayne, Ethna M MacCarthy, J N Greene, E D Khan, A F Crowley, A G Lee, Margaret F Y Dixon, Alicia G Pike, H H Robinson, T J N Bates, J D Dennehy, A R B Jackson, J B Dunlop, and G F Shaw

Medicine—J D Whiteside, David Selman, F L Willington, C B Robinson, G F N Anderson, Sylvia M Hall, Muriel

Bannister, J K Craig, L E Morris, and C W Bradfield (second-class honours), E Lucas M E FitzGerald, Samuel Fine, W L Bamford, J O G Moore R G P Heard, Matthew Daly, A H Isaacson, G S Sheill Kathleen Dowling, B S Good Olive S H Devlin, T N Arthur N J Hogan, Tom Shier, Matthew Shreider, Jack Freedman, Arthur Graham, W F Carpenter, D W McCarthy, A C Corbett, E F Keating, N G Brown, G H Rutherford, G A Anderson, D L Harbinson, Frances M C Wolfe, and G E P Kelly

Surgery—C B Robinson, Sylvia M Hall, R S W Baker, and F L Willington (second-class honours); P M Goedvolk, J K Craig, H D Chomse, J D Whiteside, A O Corbett, J P Gore Grimes, E G Hobart, F A Hanna, Frank deBurgh Whyte, M Waters, Myer Herman, W B Welply, W F Carpenter, Maureen C Johnston, Arthur Graham Matthew Daly, L E Morris, Edward Cullen, H S Boyce, and D W McCarthy

Midwifery—H H Balch and J R Healy (second-class honours), William Jones K T Acton, P C Denham, R W Carey, E G Millar T H Downes, Moira M Mallagh, F J Queally, M N O Riordan, Phoebina Eakins, and R M Hallahan

DIPLOMA IN GYNÆCOLOGY AND OBSTETRICS

R. A Fairley, W F Joynt, and H M Ayoub (second class honours), and M A Abed

D P H

Part I.—T S Agnew

Part II—J O Gaffney (first class honours), J G Cunningham (second class honours), and S H Morrison

D P M

Part I—J N P Moore (first class honours)

The Dr Henry Hutchinson Stewart scholarship in mental diseases has been awarded to Dr J N P Moore, the De Renzy centenary prize to Dr J C Gaffney, and the Butterworth prize to Dr F L Willington

College of Physicians of Philadelphia

The Alvarenga prize of the college has been awarded to Dr Harry Goldblatt, professor of experimental pathology and associate director of the institute of pathology of the school of medicine, Western Reserve University, Cleveland, Ohio, for his contributions to the pathogenesis of hypertension The prize is awarded to the author of the best memorial upon any branch of medicine

Society for Relief of Widows and Orphans of Medical Men

At a quarterly court of directors held on July 12, Dr C R Kempster, senior vice president being in the chair, one new member was elected, he was on his father's side the great great great-grandson of Sir George Baker, F R S, the first president of the society, and on his mother's side he bore a similar relationship to Dr James Ware, the second president A sum of £2425 was voted for the payment of half yearly grants to 62 widows and 4 orphans Membership is open to any registered medical man who, at the time of his election, is resident within a twenty mile radius of Charing Cross Particulars from the secretary at 11, Chandos Street, London, W 1

Travelling Fellowships

The Medical Research Council announce that they have awarded Rockefeller fellowships in medicine to the following candidates who intend to work at centres in the United States during the academic year 1939–40 :—

Guy Blackburn M B Camb, F R C S, demonstrator in anatomy, St Bartholomew's Hospital London

John Carson Dick M D Glasg assistant pathologist, University of Glasgow and Glasgow Royal Infirmary

John Louis Henderson M D Edin, M R C P E assistant, department of child life and health University of Edinburgh

Ronald Stanley Illingworth M D Leeds, M R C P, D P H, resident medical assistant and clinical pathologist, Hospital for Sick Children Great Ormond Street London

Robert Manoah Kark, M R C P formerly demonstrator in pathology and registrar to medical outpatients, Guy's Hospital, London

Edward Peter Sharpey Schafer M B Camb, M R C P first assistant department of medicine, British Postgraduate Medical School London

The council have also awarded Dorothy Temple Cross research fellowships to the following candidates who intend to study problems of tuberculosis at centres abroad during the academic year 1939–40 :—

Robert Roger Henderson M D Lond M R C P resident assistant physician, St Thomas's Hospital London

Arthur Harold Makins Siddons M B Camb, M R C P F R C S, chief assistant genito urinary department, St George's Hospital London

John Michael Walzer, M D Camb M R C P, medical first assistant and registrar, London Hospital

Royal Free Hospital

The A M Bird postgraduate scholarship in pathology for 1939–40 has been awarded to Dr Audrey Fraser and the Mabel Webb and A M Bird research scholarship to Dr Alice Stewart

Middlesex Hospital

The prize-giving ceremony of this school will be held at the Queen's Hall, Langham Place, London, W 1, on July 20, at 3 P M Mr S A Courtauld, chairman of the council of the school, will be in the chair Prof W B Tuck, D Sc, will deliver an address on the chemical elements, and Sir Edward Mellanby, F R S, will distribute the prizes and medals

A research fellowship in medical radiology to the value of £100 per annum has been endowed at the school by the Duke of Bedford in memory of his wife The fellowship, which is to be known as the Duchess of Bedford fellowship, is intended to further experimental research in medical radiology It is open to qualified men or women of any nationality, and may be held for a period not exceeding three years The late Duchess of Bedford was a member of the Society of Radiographers

Maudsley Hospital

Today, Friday, July 14, the Earl of Athlone, chancellor of the University of London, will open a new extension at this hospital The institution owes its inception to an offer made in 1908 to the London County Council by the late Dr Henry Maudsley to contribute £30,000 towards the cost of erecting and equipping a hospital for the early treatment of cases of curable mental illness, the provision of exact research, and the provision of medical teaching on such disorders The building was originally designed to hold 108 beds, a number which has gradually increased to 200 In one year upwards of 4000 outpatients, including children, are now seen, while the number of inpatients admitted each year has grown to between 800 and 900 A new outpatient department, special treatment blocks, additional accommodation for the central pathological laboratory, and an operating theatre were added in 1936 The present extensions include blocks for private patients in single rooms and a block specially designed for the inpatient treatment of children Conditions for admission of private patients are that they shall go of their own free will and that the outlook for recovery is good The children's block is described as a completely new departure; "nowhere in Great Britain is there specialised inpatient accommodation for children whose troubles need psychiatric investigation and treatment" A detached block has been constructed to serve as an outpatient clinic for children and is already in full work.

British Empire Cancer Campaign

At a meeting of the grand council of this campaign held in London on Monday last, the following grants were approved £400 to Mount Vernon Hospital for research by Prof T Weigert, £495 to the Strangeways Research Laboratory, Cambridge, for the salary of its physicist, and £400 to Sir Robert Muir and Dr P R Peacock for research at the Glasgow Royal Cancer Hospital by Dr Stephan Beck The total grants made this year now amount to more than £10 000

The council approved of the formation of a University of Cambridge research centre of the British Empire Cancer Campaign The initial committee to supervise this centre will consist of Dr H R Dean vice-chancellor and professor of pathology, Dr J A Ryle, regius professor of physic, Sir Gowland Hopkins F R S professor of biochemistry, and Miss Honor Fell director of the Strangeways Research Laboratory The centre will coördinate all cancer research at Cambridge and will itself initiate and direct research in the same way as the recently formed University of Oxford research centre of the campaign The council acceded to a request for affiliation from the Cancer Research Fund Committee (1934) of Northern Ireland

Mr J A Crowther Sc.D (professor of physics in the University of Reading) Mr H T Flint, D Sc (director of physics at Westminster Hospital), Dr R W Scarff (hon secretary of the scientific committee of the campaign) and Dr D G Walker (representing the British Dental Association) were elected members of grand council

An Appointment to India

Prof. F C Minett, D.Sc, director of the research institute in animal pathology at the Royal Veterinary College, London, has been appointed director of the Imperial Veterinary Research Institute of the government of India

Leverhulme Research Fellowships

A Leverhulme fellowship has been awarded to Mr. D. Ll. Griffiths, clinical assistant in the orthopædic department of Manchester Royal Infirmary Mr Griffiths will compare the radiological and histological features in bone tumours.

Amalgamation of Hospitals at Newcastle-on-Tyne

The governors of the Newcastle Throat, Nose, and Ear Hospital have decided to amalgamate the hospital with the throat and ear department of the Newcastle Royal Victoria Infirmary. The joint hospital will be housed in a new building adjacent to the infirmary.

A Visit to Germany

The offices and warehouses of Bayer Products Ltd. will be closed from noon on Friday, July 21, until 9 30 A.M. on Tuesday, July 25, when the entire staff of 150 from the London, Manchester, and Dublin offices of the firm is being taken to Germany for a long week-end visit to the Bayer laboratories at Leverkusen and Elberfeld. Urgent supplies during this period can be obtained from Messrs John Bell and Croyden, 50, Wigmore Street, London, W.1 (Welbeck 5555), or from Mr. R Woolby Brooke, 38, Gloucester Road, London, S.W.7 (Western 0123)

Appointments

AUCHINLECK, G M, L R C P, resident assistant pathologist at the Royal Free Hospital, London

BARRETT, N. R, M Chir Camb, F.R C S, surgical registrar at the Hospital for Consumption, Brompton.

BOLTON, MARJORIE, M B Lond, medical officer to the V.D. department, Guy's Hospital, London.

BONNELL, JANE, M B Lond., assistant medical officer at the Harmston Hall Colony, Lincolnshire

BOYD, MARJORIE, M D Dubl, M R.C O.G, resident assistant obstetrician at Kingston County Hospital, Surrey.

CABLL, J V, M D N.Z, M R C P, resident assistant medical officer at the Redhill County Hospital, Edgware

CLEGG, J W, M R C S, assistant in clinical pathology at the British Postgraduate Medical School, London.

COLLINS, L A, M B Camb., D.P M, assistant county medical officer for Dorset.

COMERFORD, C. H, M D Dubl., D P.H, D P.M, deputy medical superintendent at Bexley Hospital (L C.C).

CRAWFORD, A V B, M.B. Dubl., D P.H, assistant medical officer of health for Barnes.

CRAWFORD, F J. H, M D Lpool, D.P H., barrister-at-law, deputy medical officer of health for Cornwall.

FAIRLIE-CLARKE, G. A., M.B Lond., resident surgical officer at the Kent and Sussex Hospital, Tunbridge Wells.

FERRIMAN, DAVID, D M. Oxfd, M.R C P., first assistant in the medical outpatient department of the London Hospital.

FITZGERALD, E. J, M D. N U.I, medical superintendent at South Ockendon Colony, Essex.

FITZGERALD, F. P, M B Dubl., F.R C S I, assistant surgeon to the orthopædic department of the St. John Clinic and Institute of Physical Medicine, London

GOUDIE, MARGARET M, M B. Glasg., assistant medical officer for Middlesex

GRAY, CHARLES, M.B. Manc., F R C.S, first assistant in the department of surgery of the British Postgraduate Medical School, London

INSH, ALICE M, M B Glasg., assistant medical officer at the Stirling District Mental Hospital

LLOYD, O. G, M B Lond, D P.H, assistant medical officer of health for Newport, Mon

LODGE, THOMAS, M B. Sheff, D M R E, first assistant in the department of radiology, Royal Sheffield Infirmary and Hospital

MEADOWS, S P., M.D. Lond., M R C P, assistant physician to the Maida Vale Hospital for Nervous Diseases, London

MITCHELL EVELYN, M B Edin, outpatient medical officer at the Belgrave Hospital for Children, London

MOIR, A. R M., M B Edin, D P H, deputy medical officer of health for Oldham

MURRAY, C J B, M S Lond, F R C S, surgical registrar at the Radcliffe Infirmary, Oxford.

PILKINGTON, FRANCIS, M B Camb, M R C P, D.P.M, deputy medical superintendent at the Warwickshire and Coventry Mental Hospital

RACKOW, A. M., M B Lond, D M.R E, radiologist to the Evelina Hospital for Sick Children, London

SCHNITZLER, ROBERT, M.R C P E, resident assistant physician at Kingston County Hospital, Surrey

SCHOLEFIELD, G L M, M.B N Z, resident surgical officer at the Royal Masonic Hospital, London.

SEWELL, J. P., M.B Melb, D.L.O., registrar at the Central London Throat, Nose, and Ear Hospital

SHARP, H. S, M B Camb, F.R C S, chief assistant to the ear, nose and throat department, St Thomas's Hospital, London.

THOMSON, J M, M B. Aberd, senior assistant medical officer at the Isolation Hospital, Romford

TUBBS, O S, B Chir Camb., F.R C S, surgical registrar at the Hospital for Consumption, Brompton.

WALSHE, F. M. R., M.D. Lond., F.R C P., member of the civil consulting staff to King Edward VII Convalescent Home for Officers, Osborne.

*WAUDBY-SMITH, W F., M R C S., assistant school medical officer for Berkshire

*WEBB, JOSEFINE W., M.B. Lond., assistant medical officer for Berkshire

WERBELOFF, LESLIE, M B. Cape Town, D M.R E., assistant radiotherapist to the Royal South Hants and Southampton Hospital

WRIGHT, GAVIN, M B. Camb, resident anæsthetist at the Queen Elizabeth Hospital, Birmingham.

Hospital for Sick Children, Newcastle-on-Tyne.—The following appointments are announced —

OGILVIE, A. G, M.R Durh, M R C.P, hon. physician,
WATTS, WELDON, M S Durh., F.R.C S E., hon. surgeon;
KELLETT, C. E., M D. Camb, M R C P, hon. assistant physician;
DAVISON, GEORGE, M.D. Durh., M.R.C P., D C.H., hon. assistant physician; and
FEGGETTER, STEWART, M S. Durh, F.R.C.S., hon. assistant surgeon.

Colonial Medical Service.—The following promotions are announced.—

CALLANAN, J C J, M D Dubl, assistant director of medical services, Kenya,
CARMAN, J. A, M D Lond., D T.M. & H, specialist (anæsthetist), Kenya,
HAMILTON, I., M.D. Glasg., D.P.H., D T.M. & H., senior health officer, Nigeria;
HENRY, G H, L Med Dubl, medical officer, Nigeria;
MACKAY, A. G., M B Edin, D.T.M. & H, senior medical officer, Tanganyika Territory;
RAWSON, P H., M R C S, senior medical officer, Nigeria;
ROBERTS, C. E., B M Oxfd, F.R.C S E., D T M. & H., specialist, Zanzibar;
SHELLEY, H. M, F R F.P S G, M R C P., D T.M. & H., senior medical officer, Tanganyika Territory; and
SMITH, W. H., M B. Dubl., D.P H., medical officer, Kenya

Vacancies

For further information refer to the advertisement columns

Anglesey County Council —Asst. county M O.H., £600.
Banbury, Horton General Hosp —Res M O, at rate of £150
Barrow-in-Furness County Borough —Deputy M.O H and asst tuber O, £550
Bearstead Memorial Hosp, Underwood Street, E 1 —Res M.O, at rate of £100
Beckenham, Bethlem Hosp, Monks Orchard.—Res H.P., at rate of £150
Belgrave Hosp for Children, Clapham Road, S W 9 —Asst. physician
Benenden, Kent, National Sanatorium —H P., at rate of £150
Birmingham Maternity Hosp —Res M O. and registrar, £200
Blackpool, Victoria Hosp —H S to surgical unit 2, at rate of £175
Brighton, Royal Alexandra Hosp for Sick Children —H P, £150
Brighton County Borough —Sen M O. and asst. to M.O H., £900.
Burnley, Victoria Hosp —H P, at rate of £150.
Burnley County Borough —Asst M O, £500.
Cambridge, Addenbrooke's Hosp —H.S, at rate of £130
Colchester, Royal Eastern Counties' Institution —Asst M O, £350.
Coventry and Warwickshire Hosp —Res. M.O, £300.
Croydon County Borough —Asst M.O.H., £400.
Dudley, Guest Hosp —Res. surg. O, at rate of £250–£300 Also H S, at rate of £150
East Ham Memorial Hosp, Shrewsbury Road, E.7 —Hon radiologist
Essex County Council —District tuber officer, £700.
Evelina Hosp for Sick Children, Southwark, S E 1 —H S, at rate of £120
Glasgow Western Infirmary —Medical radiologist
Godalming, Surrey County Sanatorium.—First asst. M O, £570.
Grimsby and District Hosp —Res officers, at rate of £225 to £150
Harrogate, Royal Bath Hosp —Res M O, £200
Henley-on-Thames, Berks and Bucks Joint Sanatorium.—Second res asst M O £350.
Hull, Beverley Road Institution —Asst M O, £350
Hull Royal Infirmary —Second H P. and second cas. O, each at rate of £150.
Ilford, King George Hosp —Hon anæsthetist
Kettering and District General Hosp —H P, at rate of £150
Lancaster Royal Infirmary —Jun H S., at rate of £130.
Leicester, City Isolation Hosp and Sanatorium, Groby Road —Res M O, at rate of £300
Liverpool Heart Hosp, Oxford Street.—H P., at rate of £100 Also clin assts
London County Council —Sen asst M.O (grade II), £500 Asst M.O 's (class I), each £350. Also asst M.O 's (class II), each £250
London University —University readership in morbid anatomy, tenable at British Postgraduate Medical School, £800
Manchester, Ancoats Hosp —Two H S 's, one for orthopædics and one for joint post of H S to ear, nose and throat dept., and house physician, each at rate of £100.

* Subject to confirmation

Manchester, Christie Hosp and Holt Radium Institute.—Asst M O, £200 Also sen and jun res surg O's, each at rate of £150
Manchester, Langho Colony for Sane Epileptics—Med supt, £1050
Manchester, Park Hosp, Davyhulme—Res surg O, £500
Manchester, Royal Children's Hosp, Pendlebury—Res surg O and asst M O for outpatients' dept, each at rate of £150
Manchester Northern Hosp—Res H P and res H S, each at rate of £100
Manchester Royal Eye Hosp—Jun H S, £120
Manchester Royal Infirmary—Hon asst surgeon Jun asst M O in radiological dept £3.0 Med chief asst £300 Chief asst to surgical unit £250 Asst surgical officer, £70 Also H P's and H S's each at rate of £50
Manchester Victoria Memorial Jewish Hosp—Part time clinical pathologist, £200
Mansfield and District General Hosp—H P at rate of £150
Margate and District General Hosp—Res M O, £150

SOCIETIES

ROYAL SOCIETY OF MEDICINE 1, Wimpole Street, W 1
TUESDAY.—5.30 P.M general meeting of fellows
WEST LONDON MEDICO-CHIRURGICAL SOCIETY
TUESDAY—5 P.M (West London Hospital, W 6), general meeting

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

BRITISH POSTGRADUATE MEDICAL SCHOOL Ducane Road, W 12
TUESDAY—4.30 P.M, Sir Arthur Hall Meningitis and Acute Infections of the Central Nervous System
WEDNESDAY—Noon clinical and pathological conference (medical) 3 P.M, clinical and pathological conference (surgical)
THURSDAY—2.15 P.M Dr Duncan White radiological demonstration 3.30 P.M, Dr A A Moncrieff Hygiene of the Newborn Child
FRIDAY—2 P.M, clinical and pathological conference (obstetrics and gynæcology) 2.30 P.M, Mr J D Hume Hernia and Its Treatment
Daily 10 A.M to 4 P.M, medical clinics surgical clinics and operations obstetrical and gynæcological clinics and operations

Births, Marriages and Deaths

BIRTHS

DARBISHIRE.—On July 8, at Bowness-on-Windermere, the wife of Dr S B Darbishire—a daughter
DUNLOP.—On July 10, the wife of Dr J Leeper Dunlop of Tetbury, Glos—a son
FISHER.—On July 3, at Abingdon, the wife of Dr J H Fisher—a son
MACEWAN.—On July 7, the wife of Dr Alastair MacEwan, of Llandudno—a daughter
MONTGOMERY SMITH.—On July 4, the wife of Dr W Montgomery Smith, of South Norwood—a daughter
RIVERS MOORE.—On July 4 at Port Shepstone South Africa, the wife of Dr Francis Rivers Moore—a daughter
SMALLHORN.—On July 5 at Ruskington, Lincolnshire, the wife of Dr Thomas Smallhorn—a son

MARRIAGES

HERTEN GREAVES—PORTER.—On July 8 at All Souls' Church, South Hampstead Edgar C Herten-Greaves, F R C S, to Patricia Margaret Porter
SPRATT—BARRY.—On July 1, at St Ethelburga's, London Leslie Spratt, M B, to Gladys Ida Barry
TAYLOR—BARBOUR.—On July 8 at St Andrew's Presbyterian Church Cheam, Robert Bicket Taylor, M B to Phyllis Jean Barbour

DEATHS

BLAIR.—On July 8, at Claygate, Surrey, Charles Samuel Blair, M D Durh, F R C S late of Richmond
BROWN.—On July 9, at North Bersted, Sussex, David Brown, M B R U I, of Tientsin N China.
BUCHANAN.—On July 9 at Watford, James Ronald Buchanan, M B Lond, in his 37th year
BUCKLAND.—On July 8, at Bournemouth, Francis Oke Buckland, M D Edin, aged 81
ELLIS.—On July 8 at Hintlesham, Suffolk, Henry Havelock Ellis, L.S.A, F R C P in his 81st year
HAMILTON.—On July 8 at St. Thomas's Hospital, Dennis Godfrey Hamilton, M R C S
HOLROYDE.—On July 2 at the Citadel Military Hospital, Cairo George Graham Hedingham Holroyde, M C, L.M.S.S.A., lieut-colonel R.A.M.C
MADDICK.—On July 6, Edmund Distin Maddick, C.B.E, F R C S.E, of Hove, aged 85
PURDIE.—On July 7, James Purdie, M B Glasg, of Brentford, aged 49
RECKITT.—On July 8 at Hatch End, Middlesex Edward Bass Reckitt, V D M D St And, lieut-colonel R.A.M.C(T), retired late of Little Hadham, Herts aged 87
SUMPTER.—On July 4, at Sheringham, Walter John Ernely Sumpter, M D Durh

N.B.—A fee of 7s 6d is charged for the announcement of Births Marriages and Deaths

THE LANCET 100 YEARS AGO

July 13, 1839, p 572

From William Farr's letter to the Registrar General on the first annual report of births, marriages and deaths

The registration of the causes of death, besides contributing to practical medicine, will give greater precision to the principles of physic Loose phrases are still current, for which numerical formulæ will be substituted Sydenham, one of the most accurate of medical writers, in speaking of small pox employed such terms as these (1661) "It provailed a little, but disappeared again" (1667–9) "The small pox was more prevalent in town for the first two years of this constitution then I ever remember it to have been" (1670–2) These terms admit of no strict comparison with each other, The present registry will furnish medical science with an unbroken series of observations expressed numerically

NOTES, COMMENTS, AND ABSTRACTS

JENNER AS ROYAL PHYSICIAN

THE fact that Edward Jenner was appointed physician extraordinary to George IV is omitted from most accounts of his life, including those given in the Dictionary of National Biography and the Encyclopædia Britannica. Nor is any reference to it made in the latest study of him, reviewed in these columns on Nov. 11, 1933 (p. 1093). In the best documented of all biographies of Jenner written by John Baron and published in 1838, his appointment seems to have been discovered after the book had been written, because there is no mention of it in the text except in an appendix of documents, nearly all of which were found in the possession of Jenner at his death, and very prominently in the title, which runs "The Life of Edward Jenner, M.D., LL.D., F.R.S., Physician Extraordinary to His Majesty George IV. . . ." The document is listed thus: "1821. LONDON. March 16.—Appointment of Dr. Edward Jenner to be Physician Extraordinary to the King of Great Britain." Possibly, or even presumably, Jenner attended a member of the royal family for the purpose of vaccination. Queen Victoria was vaccinated in 1819, but we have not traced her vaccination to Jenner. The fact that Jenner was a very sick man in 1821 and died in 1823 may be the reason why his appointment was afterwards overlooked.

Baron's statement has received confirmation by the sale for £21 10*s* at Sotheby's on June 12 of the original manuscript oath signed by Jenner in 1821 on his appointment as physician to George IV, together with a letter from Jenner returning the documents. At the same sale a letter from Marcello Malpighi to Cardinal Gastaldi in 1684, containing a diagnosis and prescription for the cardinal's sister, fetched £7 10*s*., and nineteen letters (about thirty pages) from Lazaro Spallanzani on scientific subjects, 1766–93, were sold for £28.

THE BRAIN MADE EASIER

IN presenting what he calls "a materialistic conception of brain as an instrument of mind," Dr. R. J. Berry of Stoke Park Colony, Bristol, has attempted to describe in simple language and within the compass of a small book the structure, evolution and development of the human brain (Your Brain and its Story. London: Humphrey Milford, Oxford University Press. 1939. Pp. 165. 7*s*. 6*d*.). Written in lively style, the book opens with a biological summary of the development of nervous systems, starting with those of primitive and simple animals. There follows an interesting chapter on the basic types of brain and their recapitulation in man, and the author goes on to discuss, among other things, the twin nervous systems, the service of the senses, and how the brain works. The closing chapters deal with mental defect, its correlation with the size and demonstrable pathology of human brains, and some of its regrettable effects on human behaviour. Mr. H. D. Steele illustrates the book with many beautiful and accurate drawings. Unfortunately the complexity of the subject makes an exposition fully comprehensible to the layman almost impossible, but Dr. Berry has nearly achieved it.

TRANSFUSION SYPHILIS

No doubt there are many more cases of syphilis insontium than are revealed. Another example of conveyance of infection by blood-transfusion is recorded by F. Ronchese (*New Engl. J. Med.* 1939, 220, 556). The patient was a boy of 13 who urgently required a transfusion for cachexia. The blood of the donor, a friend, was tested for agglutination, but no Wassermann examination was made. The transfusion was a striking success, but the boy developed a secondary rash in a few weeks, and it turned out that the donor had had a penile sore at the time he gave his blood.

Ronchese has questioned a number of American hospitals about their procedure with reference to serological testing of blood-donors. The answers to the questionnaire, if given at all, were often unsatisfactory and at best the donors were tested only every six months. Ronchese insists that much greater care should be taken and goes so far as to suggest that serological and physical examinations should be made immediately before every transfusion.

THE UNIT OF PRACTICE

"More importance," said Sydenham, "is to be attached to the desires and feeling of the patient, provided they are not excessive or dangerous, than to doubtful and fallacious rules of medical art" Prof. D. W. Propst of Illinois takes this as the text of a book written with the object of systematising his own knowledge of the general principles underlying the practice of medicine and of arranging that knowledge in a form palatable to students (The Patient is the Unit of Practice. Springfield, Illinois: Charles C. Thomas. 1939. Pp. 219. 16*s*.). The first part is concerned with the nature of disease, with constitution and heredity, man's adaptability to environmental changes, and his failure so to adapt, resulting in disequilibrium. The second deals with diagnosis—"the working hypothesis of the clinician"—and the third with the basic therapeutic principles of practice: rest, diet, symptomatic treatment and psychotherapy. The reader is reminded of Allbutt's words, that the patients and not the diseases are the entities. This is one of the lessons to be learnt from a book, which, though it contains nothing strikingly original, is nevertheless a useful digest of much of that vaguely appreciated knowledge, steadily acquired and often subconsciously applied during a clinical lifetime.

MEDICAL JOURNALS AND BOOKS FOR CHINA

Dr. JOAN MCMICHAEL writes:—"The China Medical Aid Committee has recently received an appeal from Dr. Lim of the Chinese Red Cross Training School, at Kweiyang, for medical journals and medical and surgical textbooks. This training school, in the words of its own report, 'is attempting, in the fire of war, to build a firm base for the national health service of the new China' It cooperates with the Chinese Red Cross, the Army Medical Service Corps, and the National Health Administration.

"Many of your readers who do not file back issues of their medical journals would doubtless be willing for them to be used in such a cause. May I therefore take this opportunity of appealing through your columns to the profession both for medical journals (numbers for the past two years would be most welcome) and for medical textbooks suitable for the training of young doctors, nurses, dressers, and ambulance units? Surgical and first-aid textbooks are most urgently required, but any good recent (within the last five or ten years) textbooks would be gratefully accepted. Journals and books should be sent to Dr. Joan McMichael, Organising Secretary, China Medical Aid Committee, 121, Westbourne Terrace, London, W.2. Journals may be sent monthly, or collected and sent for several months together. All books and journals will be forwarded direct to China, and the British Fund for the Relief of Distress in China, to which we are affiliated, is able to secure free carriage for us."

THE MEDICAL DIRECTORY.—Messrs. J. and A. Churchill Ltd write: "To maintain the accuracy of our annual volume we rely upon the return of our schedule, which has been posted to each member of the medical profession. Should the schedule have been lost or mislaid we will gladly forward a duplicate upon request. The full names of the doctor should be sent for identification." Messrs. Churchill's address is 104, Gloucester Place, London, W.1.

ADDRESSES AND ORIGINAL ARTICLES

THE MECHANISM OF DIABETES MELLITUS*

BY H P HIMSWORTH, M D Lond, F R C P
DEPUTY DIRECTOR MEDICAL UNIT UNIVERSITY COLLEGE HOSPITAL, LONDON

III—HUMAN DIABETES MELLITUS

UP to, and for some time after, the discovery of insulin it was tacitly assumed that all cases of human diabetes could be explained by deficiency of insulin, but during the last decade suspicions have arisen regarding the correctness of this assumption These suspicions had their origin in clinical experience which compelled the realisation that the efficiency with which insulin acts in different patients, and in the same patient in different states of health, varies considerably This disclosed the possibility that a state of diabetes might result from inefficient action of insulin as well as from lack of insulin

DIFFERENTIATION INTO TYPES

Most important clinical observations have been made in this field by Falta and his colleagues [40 41] Using four different tests Falta claims to have differentiated diabetes into two types (1) the insulin sensitive type, which requires little insulin to prevent the excretion of many grammes of urinary sugar, tolerates little or no increase in insulin dosage without showing hypoglycæmic symptoms, and reacts to withdrawal of treatment by profuse glycosuria, and (2) the insulin resistant type, which requires many units of insulin to deal with each gramme of urinary sugar, tolerates many units of insulin above the dose required to keep the urine free of sugar, and on cessation of treatment shows little or no glycosuria The response to the tests does not, however, permit a clear differentiation of diabetics into two groups, and most cases occupy an intermediate position between the extreme insulin sensitive and the extreme insulin resistant patients

The work, previously discussed, on the effect of dietetic variations on insulin action demonstrated that the efficiency with which insulin acted depended on the factor of insulin-sensitivity, and this suggested the possibility of a type of diabetes due to insensitivity to insulin It was speedily found that comparison of the effects of injected insulin on the blood sugar of different diabetic patients was impracticable owing to the influence of the wide variations in the fasting blood sugar level, and a new test was sought which would overcome this difficulty This has been found in the application of the observation, previously made on animals [42] and since confirmed on man,[43] that the effect of insulin in suppressing hyperglycæmia due to administration of glucose is determined by the sensitivity to insulin The insulin glucose test consists of injecting intravenously a dose of insulin (5 units per square metre of body surface) and immediately afterwards giving a dose of glucose (30 g per square metre of body surface) by mouth Blood sugar estimations are made before, and at short intervals during the first hour after, the insulin and glucose are given Diabetic patients give two distinct types of response to this test [44] (fig 7) (1) the insulin sensitive type, in which the injected insulin comes into action immediately and suppresses the alimentary hyperglycæmia, and (2) the insulin-insensitive type, in which the injected insulin comes into action slowly and weakly and suppresses the alimentary hyperglycæmia to only a slight extent In the investigation of the significance of these two types of response the insulin glucose test was compared with the blood sugar glucose tolerance curve under the same conditions and after the same dose of glucose

The blood glucose tolerance curve can be measured for purposes of comparison by the area enclosed by it and the fasting blood-sugar level. When the blood glucose tolerance curve and the insulin glucose curve, obtained from the same patient under the same conditions, are drawn on the same graph, the area between represents the effect of the insulin injected in the insulin glucose test This area is called the insulin area (I), and the ratio between the insulin area (I) and the glucose tolerance area (G)—the I/G ratio—is a measure of the sensitivity to insulin of the particular subject When the I/G ratio is low, the sensitivity to insulin is diminished, when it is high, sensitivity is increased [45] This ratio has the great advantages that it is little affected by minor experimental errors, and that it allows for the effect of hyperglycæmia in facilitating insulin action It does not, however, take into account the height of the fasting blood sugar level at which the tests are performed, and it therefore remains a measure of sensitivity to insulin at a particular blood sugar level In insensitive diabetics the average value of the I/G ratio is 0 51 (with a standard deviation of the series of 0 11) The lowest value of the I/G ratio in the insulin sensitive diabetics is 0 98—1 0, nearly four times the standard deviation distant from the mean of the insulin insensitive cases The two groups of cases are, therefore, clearly differentiated and do not merge into each other [47] Using their own modification of the insulin glucose test, de Wesselow and Griffiths [21] have stated that all grades of response from a typical sensitive to a typical insensitive may be obtained. This conclusion is due to their modification of the test failing, owing to infrequent blood sampling, to differentiate between the two types of response The insensitive type of response is clearly demarcated from that of the sensitive type

When one comes to consider the clinical features of the cases giving the different responses to the insulin glucose test, it is found that, although there is a typical clinical group of cases giving each type of response, cases clinically atypical are frequently encountered in either group On the whole the sensitive diabetics tend to be younger and thin and to have a normal blood pressure and normal arteries, and as a rule their disease is of sudden and severe onset The insensitive diabetics, on the other hand, tend to be elderly and obese and to have hypertension and arteriosclerosis, and in these patients the onset of the disease is insidious These two groups of diabetics are identical with the cases typical of the two groups distinguished by Falta's tests,[40 41] and he also has found that cases are frequently met with in one group which clinically are typical of the other group A clearer clinical distinction of the diabetics giving the two different responses to the insulin glucose test is found in regard to the reaction of the different groups to treatment Kerr and I have found, as Falta

* The Goulstonian lectures for 1939 delivered before the Royal College of Physicians of London on March 2, 7, and 9 Lect I and the first and second parts of II appeared in THE LANCET of July 1 8 and 15 respectively

has,[40] that sensitive diabetics easily respond to an overdose of insulin and speedily develop ketosis if treatment is insufficient, whereas the insensitive type can tolerate a relatively large excess of insulin without showing symptoms of overdosage and rarely develop ketosis

The two groups of diabetics appear to react differently to dietary changes. In the experience

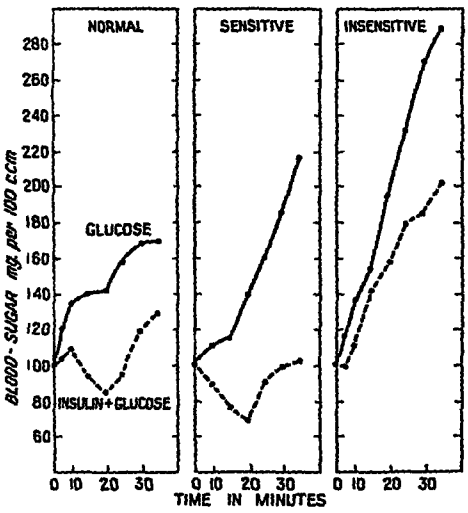

FIG. 7 — Glucose-tolerance and insulin-glucose curves from a normal subject, from an insulin-sensitive diabetic, and from an insulin-insensitive diabetic. The composition of the diet was approximately the same in each case.[67]

of Dr. Kerr and myself increase of dietary carbohydrate in the treated sensitive diabetic produces no increase in glycosuria or insulin requirements, whereas in the treated insensitive diabetic such a change increases glycosuria and consequently increases the insulin requirements.[67] We are in some disagreement with Falta on this point. At first he thought that the effect of carbohydrate in his two groups of diabetics, which we assume to correspond to our two groups, was the reverse of our findings, but recently he has modified his opinion and stated that increase of dietary carbohydrate may not unbalance sensitive diabetics.[40] MacBryde,[99] using Falta's tests, has agreed with Falta's original opinion, but his periods of observation on each diet were too short to allow stabilisation after each dietary change, and his published results, so far as they go, can equally well be interpreted as showing the opposite of what he claims. In support of our findings we have observed that increase of dietary carbohydrate in sensitive cases tends to cause a fall in the fasting blood-sugar and an improvement in the glucose-tolerance curve, whereas in insensitive diabetics the reverse tends to happen. In sensitive cases and in normal subjects increase of dietary carbohydrate produces an increased sensitivity to insulin, as judged by the increase in the value of the I/G ratio, whereas in insensitive patients little or no change in sensitivity takes place.[67] But it has not been possible to change one type of diabetic response into the other by altering the composition of the diet. Card[20] found no effect of variation in dietary carbohydrate on the insulin-depression curve in diabetics. Within the range of dietary variation that he studied little effect would have been discovered even in normal subjects.

Our results on the different effect of diet on the two types of diabetics appear to offer a means of reconciling the two conflicting schools of thought on the dietetic treatment of diabetes. One school maintains that the best results and economy in insulin dosage are obtained with low-carbohydrate diets; the other that better results are obtained with high-carbohydrate diets, and that such diets do not necessitate increase of insulin dosage. If our findings are correct, it is clear that increase of dietary carbohydrate will increase the insulin requirements of insensitive diabetics, whereas in sensitive cases it will cause either a reduction or no change in the insulin dosage. We emphasise, however, that, although insensitive diabetics may require less insulin on a low-carbohydrate diet, this is no proof that such a diet is the optimum for these patients.

The slight effect of insulin in suppressing alimentary hyperglycæmia in the insensitive type of patien may result from one of two causes: an impairment of the action of insulin in accelerating removal of blood-sugar in the peripheral tissues, or a masking of insulin action by excessive secretion of sugar by the liver. In man an indication of the effect of insulin on the peripheral removal of sugar can be obtained by measuring the changes in the capillary-venous blood-sugar difference. It was found by applying this method to the insulin-glucose test that in the normal subjects and sensitive diabetics insulin greatly accelerated the rate at which the peripheral tissues removed sugar from the blo whereas in the insensitive patients little acceleration of the rate of removal resulted.[66] This work has been confirmed by Marble.[99 100] Griffiths[51] finds the peripheral effect of insulin reduced in all diabetics but more so in insensitive than in sensitive cases. It appears, therefore, that in the sensitive diabetic, as in the normal subject, insulin increases the removal of sugar from the blood by the peripheral tissues, whereas in the insensitive diabetic this action is impaired.

The question now arises as to what is the essential difference between the two types of diabetics. In the insulin-sensitive diabetic administration of insulin turns the diabetic sugar-tolerance curve into an essentially normal insulin-glucose curve (fig. 7), and this suggests that the disease in this type of case is due to lack of insulin. Supporting this conclusion is the apparently normal action of insulin in the peripheral tissues of sensitive patients, their rapid clinical response to insulin and the demonstration, by the I/G ratio, that such cases behave as would be expected were there a deficiency of insulin.[67] In the insensitive cases, on the other hand, the insulin-glucose response suggests some interference with the action of insulin, and the low values of the I/G ratio show that these cases are less sensitive than normal to injected insulin. Further, the impairment of insulin action in the peripheral tissues has been demonstrated, and from theoretical considerations it has been shown that the quantitative effect of insulin in such cases is such as would be expected were the disease due not to lack of insulin but to insensitivity to insulin[67] (fig. 8).

Up to this point we have been considering only the events during the first hour of the glucose-tolerance and insulin-glucose curves—i.e., the rate at which the injected insulin comes into action rather than the total effect If the curves are prolonged to three hours, the change in the insulin area indicates the total effect of the injected insulin. In sensitive diabetics and normal subjects insulin action is strong

during the first hour and has diminished considerably by the third hour In insensitive diabetics, on the other hand, insulin action is relatively weak during the first hour, strong in the second, and only little less in the third The result is that in the two types of case the total action of insulin differs relatively little, whereas the rate at which insulin comes into action differs considerably [67] This suggests that insulin is not destroyed more rapidly in the insensitive diabetic, but merely that it comes into action more slowly Such a conclusion would be compatible with the insulin insensitivity being due either to the presence of a retarding but not destructive inhibitor of insulin or to the relative lack of an activator or coenzyme of insulin These possibilities are not mutually exclusive The fact that the total action of insulin is not grossly different in the two types of cases explains two otherwise puzzling clinical points—namely, that the total insulin requirements in insensitive diabetics are not on the average higher than in the other group, and that, when extra carbohydrate is added to the diet of insensitive patients, the daily increase in glycosuria is only a fraction of the excess ingested

Some interesting results on the utilisation of glucose in different diabetics have recently been presented by Newburgh and his co workers,[105] who found that in young thin diabetics the capacity to oxidise glucose was reduced, whereas in elderly obese diabetics the capacity was normal Diabetics of this latter type are usually insensitive, and observations on the absolute effect of insulin in these latter patients are relevant to Newburgh's results. In the normal subject the effect of insulin on alimentary hyperglycæmia is approximately proportional to the

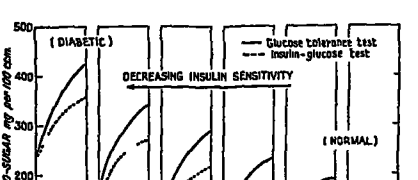

FIG 8—A series of diagrams showing the effect of decreasing insulin-sensitivity on the blood glucose tolerance curve and the insulin glucose curve The series depicts responses grading from those of a normal subject to those of a frank insulin insensitive diabetic

degree of hyperglycæmia on which it acts when insulin sensitivity is kept constant by giving a diet of the same composition In insensitive diabetics receiving the same diet this proportionality breaks down, but the amount of blood sugar removed by insulin in insensitive patients remains in most cases practically the same as in normal subjects despite the increased hyperglycæmia on which the insulin is acting (fig 8) Thus at hyperglycæmic levels the effect of insulin on the majority of insensitive diabetics is approximately the same as at lower levels in normal subjects This indicates that the elevation of the blood sugar in insensitive diabetics is adequate to compensate for the diminished ability of the tissues to deal with carbohydrate under the influence of insulin It is not improbable that, when the disease is thus compensated, the ability to oxidise ingested carbohydrate is only slightly impaired The relatively mild clinical course in such patients is readily understandable on the basis that in them diminished ability to deal with carbohydrate is largely compensated In the sensitive diabetic, in whom disease is thought to be due to lack of insulin, the situation is different Diminished ability to deal with carbohydrate consequent on lack of insulin appears usually to be more severe than when this disability is due to insensitivity to insulin, and consequently adequate compensation often is not achieved In the absence of adequate compensation it is not surprising that the ability to oxidise ingested carbohydrate is impaired, and that the clinical course in such patients is severe and if untreated ends rapidly with death in diabetic coma

NATURE OF INSENSITIVITY TO INSULIN

The diabetes developing in acromegalics [41] and in cases of Cushing's syndrome [67] is of the insulin-insensitive type as judged by the insulin glucose test The following case illustrates the extreme degree of insulin insensitivity in such cases and its apparent amelioration by X-ray irradiation of the pituitary gland.

A woman aged 40, a patient of Dr Charles Miller, presented a classical picture of Cushing's syndrome, and she had had mild diabetic symptoms during the previous nine months A total dose of 25 units of insulin daily was sufficient to clear the urine of ketones, but she still continued to pass large quantities of sugar Her fasting blood-sugar level averaged 142 mg per 100 c cm , and her glucose tolerance curve was frankly diabetic The insulin glucose test was of the insensitive type, the I/G ratio being 0 39 X-ray irradiation of the pituitary region was carried out, and the patient rapidly became sugar-free and remained so, even when the dose of insulin was gradually reduced to 5 units daily.

On readmission to hospital ten months later her fasting blood-sugar level, when she was receiving the same diet as previously but no insulin, averaged 102 mg per 100 c cm , but her glucose-tolerance curve was still of the diabetic type Her sensitivity to insulin had, however, increased, with the result that the I/G ratio had risen to 0 67, the normal average for her age-group being 0 86 Concurrently with this improvement in the diabetic condition the blood-pressure fell from an average of 175 mm to an average of 120 mm Hg, and menstruation became regular

Since this time a further course of irradiation has been given, the blood-pressure now averages 105 mm , and she remains sugar-free without taking insulin. In this case, with the institution of measures directed against the hypophysis, the clinical condition improved and concomitantly her sensitivity to insulin increased

Extracts of the anterior hypophysis produce, when injected into normal animals, a syndrome resembling diabetes mellitus and an insensitivity to insulin. By injection of crude extracts into normal rabbits diabetic sugar tolerance curves and an insulin insensitive type of response to the insulin glucose test can be produced

Many claims have appeared in the medical journals recently of the isolation from the blood or urine of groups of diabetic patients of substances which antagonised insulin action None of the claims has received adequate confirmation , some have been refuted It is of interest that no trace of any substance with the properties found in extracts of the anterior hypophysis can be demonstrated in the blood of animals rendered completely insensitive to insulin by the injection of such extracts The

single case reported by Glen and Eaton [48] requires notice, however, as of exceptional interest The patient was a diabetic who was extremely resistant to insulin, and injection of her serum into rabbits produced a state of insensitivity to insulin which resembled in many respects the resistance produced by anterior-pituitary extracts.

ANTERIOR-PITUITARY GLAND AND PRODUCTION OF DIABETES MELLITUS

The most striking work on the production of diabetes since von Mering and Minkowski demonstrated the effects of pancreatectomy has been initiated by Houssay's researches on the anterior-pituitary gland Houssay early showed that injection of extracts of this gland produced temporarily a diabetic [73] state, and recently Young [140 141] has shown that injection of increasing doses of these extracts into normal dogs produces a state of permanent diabetes This effect is produced by crude saline extracts of the fresh gland By fractionation these crude extracts can be separated into two parts: (1) the glycotropic factor, which antagonises the action of insulin but does not produce on injection into normal animals either a rise of blood-sugar or diabetes, and (2) the diabetogenic fraction, which also antagonises insulin but in addition raises the blood-sugar produces ketosis, and on continued injection ultimately leads to permanent diabetes. The sequence of events on injection of the diabetogenic extract is significant. After two or three days glycosuria, hyperglycæmia, and some degree of ketosis appear, but, if the daily dose of extract is not increased, these disappear spontaneously in a further few days. By increasing the dose of extract as soon as the glycosuria begins to fall, a sustained hyperglycæmia and ketosis can be maintained, and after two or three weeks of injection diabetes results. While receiving injections the animal steadily gains weight If at any time during this period the injections are stopped, the animal reverts to a normal state The diabetes ultimately produced is severe Glycosuria, ketonuria, and hyperglycæmia are considerable but easily influenced by the diet Glycosuria is increased by carbohydrate administration and decreased by its restriction Ketonuria is increased by a fatty diet but to a greater extent by a protein diet. These diabetic dogs can live for long periods without insulin, but, if insulin is given and then suddenly withdrawn, death in coma may result Biopsy and autopsy specimens of the pancreas show degeneration of the islets of Langerhans, [112] and Best and Campbell [12] have found no appreciable quantity of insulin in the pancreas of such animals

Perhaps the most important aspect of Young's work lies in its having suggested a new principle in pathology He has shown that injection of extracts which in single doses produce transient diabetes may, if repeated during a relatively short time, produce permanent diabetes. The possibility is thus raised that a short period of over-function in an endocrine gland may lead to a permanent derangement of body function, and that this derangement may be, at least in part, due to lesions of a second endocrine gland If this be so, the failure to demonstrate excess of anterior-pituitary factors in established cases of diabetes mellitus or of Graves's disease may be explicable, although it is possible that such factors may be demonstrable during the period when the disease is developing

It is of interest to consider Young's experimental diabetes and the clinical diabetes associated with known lesions of the anterior-pituitary gland A case has previously been reported of a woman suffering from diabetes mellitus and Cushing's syndrome in whom the diabetes was alleviated by X-ray irradiation of the pituitary region; but this desirable result is not always obtained, and as an example of this failure the following case may be cited

The patient, a woman aged 46, was known to have had glycosuria, hypertension, and amenorrhœa for the previous eight years. On examination she was seen to be red-faced and fat, especially on the trunk, and had a few cutaneous striæ on the lower abdomen. Her sugar-tolerance curve showed definite but moderate diabetes. Several courses of X-ray treatment to the pituitary region produced a fall in blood pressure from 270 mm. to 180 mm. Hg, lasting six *months*, but *the glycosuria steadily* increased, with the result that now she requires insulin.

It is possible that this case may have been due to suprarenal cortical tumour, but the fall in blood pressure, when the pituitary region was irradiated, gives some weight to the opinion that the pituitary gland was concerned in her condition. The different result in each case of irradiation may perhaps be explained as follows. In the first case the irradiation was given before diabetes was established at a time corresponding to the period of injections in Young's dogs In the dog cessation of injections at this stage allows the metabolism to return to normal; in the patient at a similar stage restriction of secretions of the diabetogenic factor by the hypophysis would, if it occurred, be expected to produce a similar result In the second case irradiation was not given until the diabetes was established at a time corresponding in Young's dogs to the stage when injections have ceased and permanent diabetes with lesions of the islets of Langerhans has been established It has been noted already that cases of diabetes mellitus associated with hyperpituitarism are insulin-insensitive. During the period of injections Young's dogs are also insensitive to insulin, but after permanent diabetes is established they are apparently insulin sensitive.[142] Whereas the diabetes of these animals during the injection stage may be due to antagonisation of endogenous insulin by pituitary factors, it is clear from the lesions in the pancreas that the permanent diabetes is due, at least in part, to insulin deficiency.

That the pituitary plays a secondary rôle as a factor in the compensatory mechanism seen in all types of diabetes has already been emphasised, but the indictment of the pituitary gland as a primary factor in ordinary human diabetes rests as yet purely on analogy In the case of insulin-insensitive diabetes this analogy is suggestive Insensitivity to insulin is characteristic of this type of diabetic, and insensitivity to insulin is produced by extracts of the anterior hypophysis.[23 73 141] By injection of such extracts into normal animals glucose-tolerance and insulin-glucose curves can be produced which are similar to those of insensitive diabetes [23] The variations in insulin-sensitivity resulting from dietary changes are mediated at least in part by the hypophysis [68] The observations that such dietary changes produce little if any effect on the sensitivity to insulin of insensitive diabetics might be expected if the disease in these patients were due to unrestrained oversecretion of the hypophysis Young's experiments very much suggest that oversecretion of pituitary factors may produce diabetes, but there is no evidence that the pituitary gland is responsible for the continuance of the diabetic state in his animals after they have ceased to receive injections At present the situation appears to be

that, although there is evidence that the pituitary gland may be responsible for the diabetes associated with hyperpituitarism, there is as yet no proof that this gland plays a primary part in the mechanism of other cases of diabetes mellitus

PATHOGENESIS OF DIABETES MELLITUS

It is definitely established that heredity [79] plays a part in the production of human diabetes mellitus, and there is evidence that obesity [80] precedes the development of diabetes in patients past middle age The suggestion that there exist two types of human diabetes mellitus raises the possibility that the pathogenesis of the syndrome of diabetes may not be the same in all patients The insensitive type of diabetes pre dominates in the older age group, and it is possibly not without significance that in normal subjects sensitivity to insulin, measured on a standard diet, decreases with age In young adult life the insulin-sensitivity, measured by the I/G ratio, averages about 1 0, and in few subjects does the value deviate far from this figure In the middle aged and elderly the average value falls to approximately 0 8, and the individual ratio ranges more widely Relative insulin insensitivity is common in and after middle life, and it is possible to collect observations ranging from mild insensitivity in normal subjects to pronounced insensitivity in definite diabetics [67] This suggests that an increasing influence of the factors making for insensitivity to insulin may ultimately produce diabetes mellitus Carbohydrate restriction is established as one of these factors, and it is perhaps possible that the long continued ingestion of a low-carbohydrate diet may precipitate diabetes mellitus There is some evidence that diabetics prefer low-carbohydrate diets, [71] and there is considerable evidence that diabetes is common in those countries and in those circumstances in which a low carbohydrate diet is taken [63] In explanation of these findings I have suggested that the hereditary predisposition to diabetes mellitus is widespread, and that in predisposed subjects the long continued ingestion of a low-carbohydrate diet may precipitate the disease [63] It has been shown that hypophysial activity is concerned in the variations in insulin sensitivity and glucose tolerance induced by changes in dietary carbohydrate [66] Young has demonstrated that *extracts of the hypophysis* can produce diabetes [140] If it can be shown that dietary changes induce the secretion of those hypophysial factors contained in the diabetogenic extracts, the above suggestion regarding the pathogenesis of diabetes may be justified But diet is not the only factor influencing insulin-sensitivity It is probable that sepsis and obesity have a similar influence, and for this reason they also may precipitate diabetes

SUMMARY

Diabetes mellitus is a disease in which the essential lesion is a diminished ability of the tissues to utilise glucose The high blood sugar in diabetes is a controlled and compensatory phenomenon, the object of which is to facilitate the utilisation of glucose by the tissues Thus hyperglycæmia is produced by increased activity of the liver, and the anterior-pituitary gland plays a prominent part in forwarding this activity The diminished ability of the tissues to utilise glucose is referable either to deficiency of insulin or to insensitivity to insulin, although it is possible that both factors may operate simultaneously Diabetes may be classified, according to which of these disorders predominates, into insulin sensitive and insulin insensitive types Insulin sensitive diabetes, which is thought to be due to deficiency of insulin, tends to be severe, and in it the *diminished ability* to utilise carbohydrate is inadequately compensated. Insulin insensitive diabetes, which is thought to be due not to lack of insulin but to insensitivity to insulin, is generally less severe, and in it the ability to utilise carbohydrate is usually more adequately compensated Certain extracts of the anterior-pituitary gland produce insensitivity to insulin, and it is possible that the diabetes associated with hyperpituitarism can be explained by oversecretion of the anterior-pituitary gland The nature of insulin insensitivity in the ordinary case of insulin insensitive diabetes has not been definitely established, and the question as to whether the anterior-pituitary gland plays a dominant rôle in its production is still open

URETERIC CATHETERISATION IN PYELITIS OF PREGNANCY

BY VICTOR W. DIX, M.B. Camb., F.R.C.S., M.R.C.P.
SURGEON WITH CHARGE OF OUTPATIENTS AND ASSISTANT SURGEON IN THE GENITO-URINARY DEPARTMENT, LONDON HOSPITAL; AND

HORACE EVANS, M.D. Lond., F.R.C.P.
ASSISTANT PHYSICIAN TO THE HOSPITAL

(With Illustrations on Plate)

INFECTION of the urinary tract is a common complication of an otherwise normal pregnancy. This fact is to be anticipated when it is recalled that dilatation of the kidney pelves and ureters, with some degree of urinary stasis, is a normal concomitant of pregnancy.

The association of pyelitis of pregnancy with urinary stasis has been known for many years and since the introduction of intravenous urography has been extensively studied by Baird (1931, 1932), Lee and Mengert (1934), and others. These workers have shown that the upper urinary tract becomes dilated in every pregnancy, the right side being the more dilated in most cases. The dilatation appears to extend upwards from the level of the pelvic brim (figs X and XI on plate). This change is first noticed between the third and fourth months of the pregnancy, becoming maximal at about the sixth to seventh month, a time at which the onset of infection is frequently observed. A great deal of work has been done in an endeavour to elucidate the factors concerned in these changes, but the exact mechanism remains obscure. It appears that the pressure of the enlarging uterus and the hypotonia of the urinary tract, which results from the hormone changes in pregnancy, must be important features.

In a paper read before the section on genito-urinary diseases at the 67th annual session of the American Medical Association in June, 1916, and later published in 1917, Caulk referred to the successful use of the ureteric catheter in what he called "large infected right renal retentions complicating pregnancy." This method of treatment is now well recognised by urologists, and a series of cases reported by Pugh in 1927 is of interest because his patients were treated by long-continued ureteric drainage and no preliminary medication had been tried. It is our experience that the great majority of patients with pyelitis of pregnancy respond to ordinary medical treatment, and we therefore reserve the use of the ureteric catheter for those cases in which, in our opinion, adequate medical treatment has failed

The routine treatment we use for these patients consists in complete rest in bed, the patient being given a light diet with as much fluid as can be taken without discomfort. There seems to be no advantage in forcing fluids in a patient who is already greatly distressed, although the fluid intake should not fall below 4 pints in twenty-four hours. In addition, potassium citrate is given in doses of 1 drachm two-hourly for eight doses, and then four hourly until the patient becomes afebrile Usually this dose is sufficient to make the reaction of the urine alkaline and to maintain it so. The reaction of a freshly passed specimen of urine should be the main guide to the dose of alkali necessary. This is best given in a simple mixture, such as pot. cit., gr. 60; syr. aurantii, ½ fluid drachm; aq ad ½ fluid ounce. It is far less nauseating than the more

complex mixtures. Occasionally diarrhœa or vomiting may result, but this may be alleviated by the use of the sodium salt or the acetate.

This treatment is usually successful, and failure, if it occurs, is often due to inadequate dosage or the use of a nauseating complex mixture. Very rarely excessive vomiting may make the administration of alkali impossible.

During the four years 1934–37 84 cases of pyelitis of pregnancy were admitted to the London Hospital, and of these only 7 required ureteric drainage—5 on account of failure of alkali therapy and 2 because of excessive vomiting.

TECHNIQUE OF URETERIC CATHETERISATION IN PREGNANCY

In this series of 7 cases nine ureteric catheterisations were carried out and all were done, with a single exception, by one of us (V. W. D.). In one patient (case 6) the second catheterisation was necessary because the first catheter was removed by a nurse when the patient returned to the ward, and in another (case 4) the second catheterisation was performed three and a half months after the first during a recurrence of pyelitis.

In no case was it necessary to use an anæsthetic, but it would be unjustifiable to conclude that catheterisation of the ureter during pregnancy is easy. From the earliest stages the irritability of the bladder makes the patient more intolerant of cystoscopy than usual, and, as pregnancy advances, the alteration in the shape and capacity of the bladder adds to the difficulties, which reach a climax when the head is engaged. When the fœtal head is impacted in the pelvis, the cystoscope is gripped firmly between it and the pubic bone, its freedom of movement is greatly restricted, and any movement is felt with more than ordinary intensity by the patient. It follows that catheterisation of the ureter, particularly in the late stages of pregnancy, should be carried out by the expert only, and it is worthy of note that in one of the cases of this series an unsuccessful attempt at ureteric catheterisation was made several hours before the successful catheterisation. If, therefore, it should ever be necessary for the relatively inexpert to attempt catheterisation in the later stages of pregnancy, an anæsthetic should be given to minimise the difficulties.

When the ureteric orifice has been identified and the catheterisation has begun there should be no difficulty, and the fact that the catheter has reached the renal pelvis will be at once evident from the rapid flow of urine, which is considerably in excess of that from a ureteric catheter of the same size passed into a normal pelvis. In those cases in which there has been a complete block at the pelvi-ureteric junction the flow may be very rapid indeed.

The size of the ureteric catheter passed has no direct bearing on the result, but it is advisable to pass as large a catheter as possible. The sizes used in this series have been 10 and 12. It is of some advantage to use ureteric catheters 10 cm. longer than the standard pattern, in order to have a greater length projecting from the vulva when the upper end of the catheter is in the renal pelvis. Great care must be taken, in withdrawing the cystoscope, to avoid displacement of the catheter. At the end of the operation the catheter is attached to the leg with a piece of adhesive plaster, and the urine is allowed to drain into a bottle.

The catheter was usually left in situ for three or four days. It is our impression, however, that equally good results might be obtained if the catheter remained for twenty-four or forty-eight hours only, although there would perhaps be a slightly increased risk of recurrence when it was removed. It should be removed at once if it ceases to run freely and gentle syringing fails to re-establish the flow.

In this series of cases we have not used therapeutic lavage through the indwelling catheter. The effect of catheterisation and drainage alone was so good that no additional treatment was needed except the continued administration of citrate.

CASE RECORDS

CASE 1.—A primigravida, aged 19, was admitted with eleven days' history of more or less constant pain in the right side of the abdomen. This was severe enough to prevent sleep and was accompanied by attacks of shivering and profuse sweating. There was no frequency or dysuria. There had been no previous kidney disease.

On *examination* she was a pale ill-looking girl. Temperature 101°F., pulse rate 114, respiration rate 24. The uterus was enlarged to the size of a thirty weeks' pregnancy. There was considerable tenderness in the right loin.

Investigations.—The urine contained 1/10 vol. of albumin, the deposit contained many leucocytes,

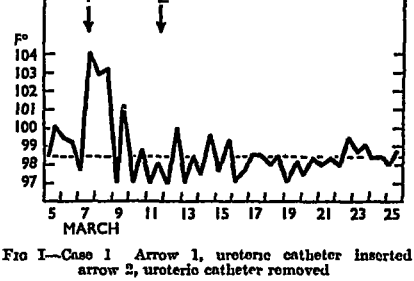

FIG. I.—Case 1. Arrow 1, ureteric catheter inserted, arrow 2, ureteric catheter removed.

occasional red cells, and bacteria, and culture produced paracolon bacilli. A blood count showed 3,600,000 red cells, hæmoglobin 59 per cent., and 17,400 leucocytes (80 per cent. being polymorphonuclears).

Progress in hospital.—Despite alkali therapy for three days her condition became worse. The pain was persistent, and on the third day she had two rigors. On the fourth day a *cystoscopy* was performed and showed that the bladder and ureteric orifices were normal. After the injection of 5 c.cm. of a 0·1 per cent. solution of indigo-carmine intravenously the dye appeared at the left ureteric orifice in four minutes, but none was seen at the right orifice. The right ureter was catheterised, and a very rapid flow of urine resulted, the first blue appearing eight minutes after the injection. There was dramatic relief of pain almost immediately. It is of interest to note that the urine which flowed out was acid, although the bladder urine had been strongly alkaline. The right-kidney urine contained pus and many gram-negative bacilli, and paracolon bacilli were grown on culture. The fever rapidly subsided (fig. 1). The catheter was left in situ for four days, the alkaline therapy being continued during and after this time. The average daily amount of urine from the ureteric catheter was 20 oz. During the same time the average amount of urine passed naturally was 29 oz. daily.

Follow through.—There were no further symptoms, and three months later she was delivered of a healthy child. Three years later she had a second and uncomplicated pregnancy. Two months after the

second confinement she came up for examination. She was completely free from urinary symptoms. The urine was clear, the deposit showed only a few epithelial cells, and a culture was sterile. An excretion pyelogram appeared normal.

CASE 2.—A woman of 23, in her second pregnancy, was admitted with fourteen days' history of pain in the right loin and attacks of shivering and sweating. For four days there had been vomiting and painful frequency. She had had rheumatic fever at the age of 14.

On *examination* she was an ill cyanosed woman. Temperature 102° F., pulse-rate 120, respiration-rate 23. The heart was enlarged, and there was an apical presystolic murmur. The blood-pressure was 120/80. There was no abdominal tenderness. The uterus was enlarged to the size of a twenty-eight weeks' pregnancy.

Investigations.—The urine had a heavy cloud of albumin, the deposit contained many leucocytes, and culture produced *B. coli communis*. The blood-urea was 21 mg. per 100 c.cm.

Progress in hospital.—This patient was treated with alkalis for four days without response. Her condition became more distressed, with right-sided abdominal pain. On the fifth day she was *cystoscoped*, and a normal bladder and normal ureteric orifices were found. After an injection of 5 c.cm. of a 0.4 per cent. solution of indigo-carmine intravenously there was no excretion from either side after eight minutes. The right ureter was catheterised, and there was a good flow of urine, which was acid to litmus. The bladder urine at the time of the examination was alkaline. The right ureteric specimen of urine contained many epithelial cells, pus cells, and bacteria. On culture there was a growth of *B coli*. The catheter was left in situ for three days, and the average daily amounts of urine from the catheter and bladder respectively during this period were 24 oz. and 32 oz. After the removal of the catheter there was complete relief for two or three days, but then for ten days the patient had occasional discomfort on the right side and slight pyrexia, up to 99.6° F. This lasted for ten days and then settled down completely (fig. II).

Follow-through.—There was no recurrence of symptoms, and five weeks later she gave birth to a healthy male child. Two weeks after the confinement the urine still contained pus and grew *B coli* on culture. An excretion pyelogram showed delayed excretion and some residual dilatation of the calyces and pelvis in the right kidney, the left being normal. When she was examined three years later the urine was clear

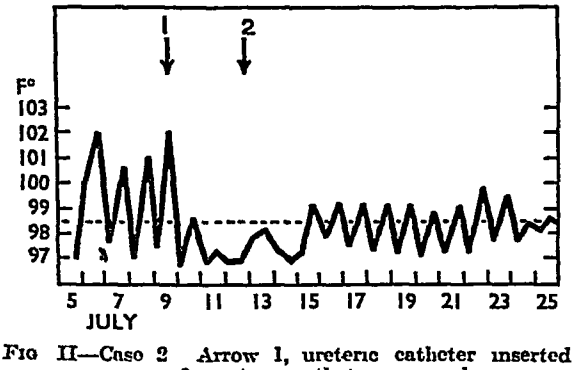

FIG II—Case 2. Arrow 1, ureteric catheter inserted, arrow 2, ureteric catheter removed.

and the pyelogram was normal except for a little rounding of the right upper calyx. There were no urinary symptoms.

CASE 3.—A primigravida, aged 23, was admitted with four days' history of pain in the right loin, gradually getting worse. She had had several shivering attacks and had vomited once. During the four days she had been ill there had been no increased frequency of micturition, although she stated that during the whole of her pregnancy she had had some degree of painless frequency.

On *examination* she was a pale ill-looking woman. Temperature 99.5° F., pulse-rate 112, respiration-rate 32. There was tenderness in the right loin, and the uterus was enlarged to the size of a thirty-six weeks' pregnancy.

Investigations.—The urine contained 1/6 vol. of albumin, there was pus in the deposit, and culture produced *B. coli communis*. A blood-count showed 5,300,000 red cells, hæmoglobin 74 per cent., and 15,000 leucocytes, of which 85.5 per cent. were polymorphonuclears. The blood-urea was 27 mg. per 100 c.cm.

Progress in hospital.—In spite of alkali treatment for five days the symptoms persisted and the temperature remained high. On the sixth day *cystoscopy* was performed and showed a normal bladder and normal ureteric orifices. There was some œdema of the internal meatus, probably due to the pregnancy. The right ureter was catheterised, and there was a very rapid flow of urine. There is no note about the reactions of the bladder and right-kidney urines at the cystoscopy. The ureteric catheter was left in situ for four days. The average daily amounts of urine from the catheter and the bladder during this period were respectively 32 oz. and 38 oz. The symptoms were rapidly relieved, and on the third day after catheterisation the patient was afebrile (fig. III).

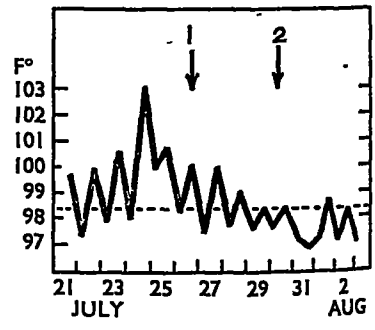

FIG III—Case 3. Arrow 1, ureteric catheter inserted; arrow 2, ureteric catheter removed.

Follow-through.—She remained free from symptoms and on the eighth day after catheterisation was delivered of a live female child. The puerperium was afebrile until she developed a breast abscess. Three months later she was admitted again, complaining of pain in the right loin and frequency of micturition. There were no abnormal physical signs. Excretion and instrumental pyelograms revealed no abnormality. The bladder urine grew *B. coli* on culture but contained no pus. The right ureteric urine was similar, and the left ureteric urine was sterile. We have been unable to trace this patient since her last admission to hospital in 1934.

CASE 4.—A woman of 23, with one child, was admitted with a three days' history of painful and frequent micturition. On the day before admission she had pain in the right loin, which rapidly became more severe.

On *examination* she was an ill-looking woman. Temperature 103° F., pulse-rate 130, respiration-rate 28. There was great tenderness in the right loin, but the kidney could not be palpated. The uterus was enlarged to the size of an eighteen weeks' pregnancy.

Investigations.—The urine was neutral and contained a cloud of albumin, pus and occasional red cells were found in the deposit, and culture produced paracolon bacilli. A blood-count showed 4,700,000 red cells, hæmoglobin 81 per cent., and 17,600 leucocytes, of which 78 per cent. were polymorphonuclears.

Progress in hospital.—She was treated for fourteen days with large doses of potassium citrate without effect. At the end of the first week a greatly enlarged and tender right kidney was palpable. On the four

teenth day *cystoscopy* was performed The bladder and ureteric orifices were normal The right ureter was catheterised, and there was at once a free flow of urine from the catheter The bladder and right

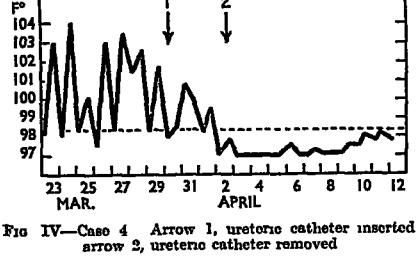

FIG IV—Case 4 Arrow 1, ureteric catheter inserted, arrow 2, ureteric catheter removed

ureteric specimens appeared to be equally alkaline The bacteriological examination showed coliform bacilli to be present in both specimens The catheter was left in situ for three days During this period the average daily amounts of urine from the bladder and catheter respectively were 54 oz and 17 oz The temperature subsided rapidly (fig IV), and the condition of the patient improved She remained free from symptoms and was discharged a fortnight after the ureteric catheterisation

Three months later she was admitted again For four days she had had painful and frequent micturition, pain in the back, and vomiting She was unable to take any medicine owing to the persistent vomiting, and *cystoscopy* was performed on the day after admission Some difficulty was found in introducing the cystoscope owing to the *fœtal head in the pelvis* The right ureter was catheterised, and there was at once a rapid flow of urine from the ureteric catheter The bladder urine contained thick pus and many red cells, and *on culture* there was a growth of paracolon bacilli The ureteric specimen also contained pus and gram-negative bacilli, and paracolon bacilli were grown *on* culture The bladder urine was alkaline, and the ureteric urine was acid The catheter was *left in situ* until the onset of labour on the fourth day after its insertion (fig V) A male child was born after a normal labour lasting ten hours Recovery was uneventful, and the *patient* left hospital on the thirteenth day after labour

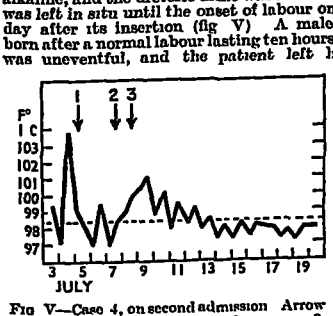

FIG V—Case 4, on second admission Arrow 1, ureteric catheter inserted, arrow 2, ureteric catheter removed, arrow 3, patient delivered

Follow-through—Two and a half years later this patient had a third pregnancy This was normal, and there were no urinary symptoms Three years after treatment in hospital she was well The urine contained no albumin, there was no deposit, and culture grew *Staphylococcus albus* only An excretion pyelogram was normal

CASE 5—A primigravida, aged 21, was admitted with a three weeks' history of pain in the right loin, which had gradually got worse For a week she had had pain on micturition, with some terminal hæmaturia

On *examination* she did not appear to be very ill Temperature 100° F, pulse rate 108, respiration-rate 26 The apex-beat was forcible, and there was a well-marked presystolic thrill and murmur The uterus was enlarged to the size of a twenty weeks' pregnancy, and the right kidney was tender on palpation

Investigations—The urine was alkaline and contained 1/5 vol of albumin, the deposit contained thick pus and many red cells, and culture produced *B coli communis* The blood-urea was 51 mg per 100 c cm A blood-count showed 5,120,000 red cells, hæmoglobin 87 per cent, and 22,800 leucocytes, of which 81 5 per cent were polymorphonuclears

Progress in hospital—She was treated with full doses of alkali but continued to feel ill and had irregular pyrexia Four weeks after admission to hospital *cystoscopy* was performed and revealed a mild cystic trigonitis, without any general cystitis The ureteric orifices were normal The right ureter was catheterised The bladder and ureteric urines were *both neutral to litmus* The bladder and right-kidney urines contained pus, occasional red cells, and bacteria, and on culture grew *B coli communis* The catheter was left in situ for three days, during which period the average daily amount of urine

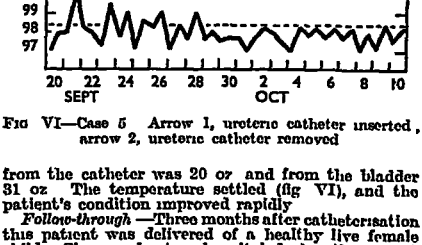

FIG VI—Case 5 Arrow 1, ureteric catheter inserted, arrow 2, ureteric catheter removed

from the catheter was 20 oz and from the bladder 31 oz The temperature settled (fig VI), and the patient's condition improved rapidly

Follow-through—Three months after catheterisation this patient was delivered of a healthy live female child She was kept in hospital during this period because of the condition of her heart Two years later she was well, with the exception of breathlessness due to mitral stenosis and auricular fibrillation A specimen of urine contained no albumin, the deposit showed epithelial cells, and culture yielded *Staphylococcus albus* only An excretion pyelogram was normal (figs XII and XIII on plate)

CASE 6—A primigravida, aged 22, was admitted with six weeks' history of slight headache in the mornings, nausea, backache, and occasional vomiting For two weeks there had been painless frequency of micturition

On *examination* she was a pale ill-looking woman Temperature 99° F, pulse rate 88, respiration rate 21 There was tenderness in the right loin on palpation, but the right kidney could not be felt The uterus was enlarged to the size of a twenty-six weeks' pregnancy

Investigations—The urine was acid and contained a heavy cloud of albumin, the deposit contained many leucocytes and red cells and amorphous urates, and culture produced *B coli communis* The blood-urea was 18 mg per 100 c cm A blood-count showed 2 800,000 red cells, hæmoglobin 51 per cent, and 6800 leucocytes

Progress in hospital—In spite of prolonged alkali treatment the temperature never settled permanently *and the patient's condition did* not improve Six weeks after admission to hospital an attempt was made by one of the surgical first assistants to catheterise the right ureter This was unsuccessful

Four days later *cystoscopy* was again performed. Some difficulty was found in manipulating the cystoscope owing to the presence of the fœtal head. Rapid inspection of bladder showed no obvious changes. The right ureter was catheterised and the specimen obtained was faintly alkaline. The catheter was unfortunately removed in error by a nurse when the patient returned to the ward. The catheterisation was then repeated and the catheter left in situ for four days. The bladder and kidney urines contained pus, red cells, and bacteria, and on culture grew *B. coli communis*. The average daily amount of urine from the ureteric catheter was 17 oz. and from the bladder 42 oz. The temperature fell at once after catheterisation (fig. VII), and the patient's condition improved.

Follow-through.—Eleven days after catheterisation she was delivered of a live male child. This case was complicated by a severe degree of anæmia of pregnancy. Two years later she was well and free from symptoms. She was six months pregnant. A catheter specimen of urine contained a cloud of albumin, there were many leucocytes in the deposit, and *B. coli* grew on culture.

CASE 7.—A primigravida, aged 24, was admitted with two days' history of vomiting followed by pain in the right loin. There was frequency but no pain on micturition.

On *examination* she was a healthy-looking woman. Temperature 102·5° F., pulse-rate 120, respiration-rate 24. There was tenderness in the right loin, and the uterus was enlarged to the size of a thirty weeks' pregnancy.

Investigations.—The urine contained 1/3 vol. of albumin, there was pus in the deposit, and culture produced *B coli communis*.

Progress in hospital.—During the first three days vomiting was excessive, making administration of alkalis impossible. For this reason right-sided ureteric catheterisation was advised. At *cystoscopy* slight general cystitis was found, and the right ureter was catheterised. This procedure was followed by relief of the symptoms in twenty-four hours. The catheter was left in situ for four days (fig. VIII). During the third week in hospital an excretion pyelogram showed a dilatation of the ureters and kidney pelves This was very obvious in the right kidney, in which one or two calyces showed excretion in the 25-min. film

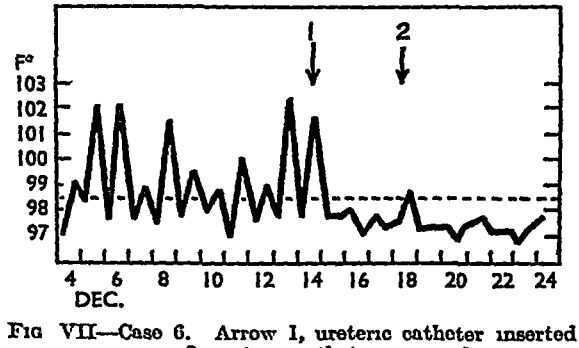

FIG VII—Case 6. Arrow 1, ureteric catheter inserted; arrow 2, ureteric catheter removed.

only. She was discharged free from symptoms after three weeks in hospital.

Follow-through.—A month later she was delivered of a live female child. She was seen again eleven weeks after the confinement. For the first eight weeks there had been some frequency of micturition, but afterwards she had remained free from symptoms. A catheter specimen contained a few leucocytes and epithelial cells and on culture grew *Staphylococcus albus* only. An excretion pyelogram was normal.

COMMENTS

This small series of cases seemed worthy of report because of the excellent response of a grave condition to a procedure which is simple and without risk in the hands of one experienced in catheterising the ureter. It must be emphasised once more that this *treatment is only demanded in rare instances* —i.e., when adequate alkali therapy has failed, as in 5 of our patients, or when excessive vomiting makes

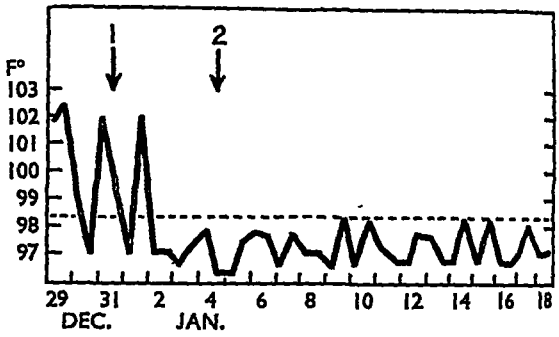

FIG. VIII—Case 7. Arrow 1, ureteric catheter inserted, arrow 2, ureteric catheter removed.

the administration of alkali impossible, as in the remaining 2 cases The obstruction factor seems to be of importance, and it is improbable therefore that any drug would have given relief without the aid of adequate drainage. It must be pointed out, however, that the sulphanilamide group of drugs was not used. Subsequent experience with this group of drugs leads us to doubt whether they would prove of any value in acute cases which fail to respond to alkali therapy, with the possible exception of those in which excessive vomiting is a factor It must be noted that the administration of alkali is continued or resumed after the insertion of the catheter.

An analysis of these cases does not reveal anything differing from the "simple" pyelitis of pregnancy. Of our patients 5 were in their first pregnancy and 2 in their second. The stage of pregnancy at which the symptoms first appeared varied between the eighteenth and thirty-sixth week. The duration of symptoms before admission to hospital varied from two to twenty-one days The right kidney was affected in every instance, and there was tenderness on examination in the right loin. In one patient (case 4) there were two separate attacks, each requiring catheterisation, during the same pregnancy

The accompanying charts show the efficacy of the treatment so clearly that little comment is necessary We wish to record that we always observed a rapid and striking improvement in the general condition of the patient after catheterisation. Premature induction of labour was not required in any of our patients, and it is probable that such a procedure should rarely, if ever, be necessary.

It is of great importance in the later management of patients who have had pyelitis of pregnancy, whether controlled by alkali therapy alone or with the aid of ureteric catheterisation, that the persistence of pus in the urine should not be overlooked. In most instances some degree of pyuria will tend to persist until after parturition. Treatment with mandelic acid may clear up such a residual infection successfully, and it should be given a trial in all cases, preferably two or three weeks after the acute phase has subsided If the pyuria persists throughout the pregnancy, many cases clear up spontaneously after parturition, but, if not, mandelic acid therapy is urgently called for. Calcium mandelate is the preparation which has been most

successful in our hands Failure to treat such residual infections after parturition may result in "subinvolution" of the urinary tract on the affected side, leading to a persistent hydronephrosis and later pyonephrosis, possibly with secondary calculi (fig XIV on plate)

With one exception (case 3) we have seen all these patients again at varying intervals after the attack of pyelitis in which catheterisation was necessary All have remained free from urinary symptoms, and excretion pyelography and examination of the urine have shown no abnormality in 5 of them, although 2 have had subsequent pregnancies The other patient (case 6) was seen at the sixth month of her second pregnancy, two years after the attack of pyelitis, and, although she was free from symptoms, her urine contained many leucocytes and *B coli* was grown on culture

A CASE OF POST PREGNANCY PYELITIS

Although the following case is not one of pyelitis of pregnancy, previous attacks had occurred during pregnancies, and the result of treatment illustrates so well the method we have described that we have included it as an additional case

A woman, aged 20, was first seen by one of us (V W D) on March 11, 1938 Her fourth child had been born two months before, and during the pregnancy she had had no trouble, although during her second pregnancy in 1932, after a miscarriage in 1934, and during her third pregnancy in 1935 she had had severe attacks of pyelitis on the right side When first seen she had an eight days' history of painful and frequent micturition, followed after two days by very severe pain on the right side In spite of intensive treatment with citrate, she continued to have severe pain, and also had several rigors

On *examination* she looked ill Temperature 103·4° F, pulse-rate 96, respiration-rate 22 There was extreme rigidity below the right costal margin and great tenderness on the right side

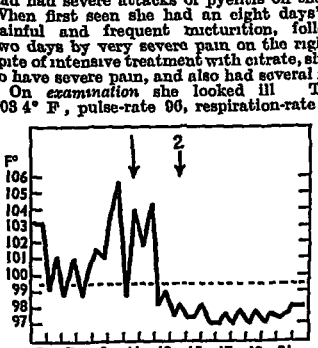

FIG IX—Post pregnancy pyelitis Arrow 1, ureteric catheter inserted, arrow 2, ureteric catheter removed

Cystoscopy showed no general cystitis The trigone was a little red and granular The right ureter was catheterised without difficulty and the catheter was left in Urine from the bladder contained a cloud of albumin, the deposit contained a small amount of pus, and culture produced *B coli* Urine from the right kidney had pus and coliform bacilli in the deposit

Progress.—On the day following catheterisation it was possible to palpate the kidney easily, although it was still slightly tender Twenty-four hours later the temperature had fallen, the kidney was no longer tender, and the patient felt well The catheter was removed on the fourth day, and there was no return of pyrexia (fig IX)

An instrumental pyelogram and an excretion pyelogram, done about a week later, showed dilatation of the right pelvis, with normal calyces and a very much dilated ureter This ureter resembled the ureter seen in cases of subinvolution following pregnancy.

SUMMARY

Seven cases of severe pyelitis of pregnancy, and one of post pregnancy pyelitis, successfully treated by ureteric catheterisation are reported. It is pointed out that this form of treatment is only demanded in those cases which do not respond to ordinary methods of treatment and that careful after treatment is necessary to avoid persistent urinary infection Premature induction of labour should rarely, if ever, be necessary, even in severe pyelitis of pregnancy

VERTEBRAL FRACTURES COMPLICATING CONVULSION THERAPY

BY HAROLD A PALMER, M.D Manc, M R C P, D.P.M.

SENIOR ASSISTANT PHYSICIAN TO WOODSIDE HOSPITAL FOR FUNCTIONAL NERVOUS DISORDERS CHIEF ASSISTANT FOR PSYCHOLOGICAL MEDICINE ST THOMAS'S HOSPITAL, LONDON

(With Illustrations on Plate)

MEDUNA, who first introduced convulsion therapy of psychiatric disorders, though he admitted that the treatment was severe, claimed that provided his indications and technique were followed carefully no serious danger was involved, and that considering the poor prognosis of the patients the procedure was thoroughly justified Some authors dismiss the complications in a few lines, referring merely to boils and coryza and temporarily and easily reduced dislocations (Harris 1938) On the other hand, there are now a number of reports of fractures involving the long bones, and in 1938 a case of fractured vertebra was reported by Wespi in Switzerland and another in this country by Stalker

In America it has lately been suggested that in as many as two fifths of patients receiving treatment one or more vertebræ are fractured In April of this year I had the opportunity of visiting the New York State Psychiatric Institute and meeting Dr Nolan Lewis, in whose department much of the work on vertebral fractures was done By that time the news had gone round the eastern seaboard of the United States and as a consequence Cardiazol therapy had been all but completely given up in many of the leading clinics

Since its inception at Woodside in 1937 an increasing number of patients have been given the treatment, and as soon as we learnt of the findings in America we began to get as many of the old patients back for radiography as possible and we radiographed all those remaining in the hospital. This gave us a total of 20 and the very first case examined revealed an almost complete compression fracture of one of the dorsal vertebræ We subsequently discovered a total of 5 cases with fractured vertebræ in the series of 20 cases The incidence here was therefore not so great as the Americans have suggested

Polatin and his colleagues (1939) have excluded the possibility of these fractures existing before

treatment by carrying out routine radiography on all their patients. Nevertheless, it is interesting that in two of the cases in which fractures were found at Woodside there was a history of severe injury One patient had had a severe fall on a ship some years ago, while the second had been involved in a motor accident within the last six months

None of the American authors give any clinical history of the patients with fractures apart from the radiological findings The following is an account of the convulsion in one of our cases

The patient was a man of 26, suffering from schizophrenia. He was given a first injection of 6 c.cm. of a 10 per cent. solution of cardiazol into the right medial basilic vein. He had a rather long aura. Then the fit began with the patient raising himself to a sitting position. His face blanched and he rotated his eyes and head to the right to such an extent as to make one feel that another half inch would result in his dislocating his neck. At the same time he cried out, and then went back slowly into a tonic contraction, working his legs as if he were riding a bicycle. His jaw opened, the gag was inserted and he bit on it firmly, and his arms went into extensor spasm with the wrists pronated. At this moment a snap was heard, which seemed to come from the patient's back about the level of his first dorsal vertebra. He then passed into the clonic phase, after which there was the usual period of apnœa succeeded by stertor. He then gradually emerged from the convulsion. During the fit a nurse was detailed to hold the patient's legs down firmly from the moment that the cycling movements started. No other restraint was applied.

It is important to mention the form of restraint used, as this may be a factor in the production of fractures Other reports do not make clear to what extent patients are restrained, but I have the impression that in America restraint is more generally employed than in this country Actually at Woodside we introduced restraint because we thought it would lessen the likelihood of dislocations and fractures It may be that by so doing we have produced the only fractures which have happened in our series

At Woodside the routine has been to give an initial dose of 5 c cm. of a 10 per cent. solution of cardiazol to all male patients, except to small men where sometimes only 4 c cm. is given; if this does not produce a convulsion a second dose 1 c cm. greater is given five minutes later. It is probable, therefore, that in the majority of cases a fit is produced by a threshold dose In the case described here we wanted to make certain of a fit because the man was not very cooperative, and in the event of failure might have refused further treatment A dose of 6 c cm may have been above this threshold and this may account for the severity of the fit The importance of not exceeding the minimum effective dose has not been much discussed in literature, but excessive dosage seems worthy of consideration as a cause of fractures

RADIOLOGICAL FINDINGS

The majority of spinal fractures recorded have been in the 4th, 5th or 6th dorsal vertebra They are compression fractures and are of all degrees of severity from a severe crush to the slightest chip off the anterior rim, or the radiogram may merely show a thin striate shadow indicating a small crack They resemble the injuries seen in miners, but they are presumably the result of severe muscular action inducing acute flexion of the spinal column It would be of much interest to examine the spines of a series of epileptics radiologically to see whether any of them show vertebral fractures. Dr F. G. Nichols's reports on the radiological findings in our cases were as follows

CASE 1.—The spine shows a compression fracture in the body of the 6th dorsal vertebra. The body shows compression and splaying out in the antero posterior view, and the lines of fracture are apparent. In the lateral view the compression is most pronounced in the anterior part of the body. There is no definite evidence of narrowing of the disks above or below. The rest of the spine shows no indication of injury.

CASE 2.—The appearances here are similar to those in case 1, only they affect both the 4th and 5th dorsal vertebræ. The 4th vertebra shows an angular compression, and the 5th complete telescoping of the body, with extensive narrowing and increased density (figs. I and II on plate).

CASE 3.—The lesion involves both the 4th and 5th dorsal vertebræ, with fractures of the anterior borders reminiscent of the appearance in osteo-arthritis, together with slight compression of the bodies (fig. III on plate).

CASE 4.—There is slight compression of the body of the 5th dorsal vertebra with slight irregularity of the anterior part of its upper border which suggests slight fissuring of the bone in this region

CASE 5.—In the anteroposterior view there is very slight narrowing of the body of the 5th dorsal vertebra. In the lateral view compression of this body is more evident and points to a fracture.

From these X-ray appearances, and from the findings of the American observers, it seems probable that there are three degrees of severity of lesion In the first a slight fracture is produced in the anterior lip of the body, in the second there is a minor degree of compression with striæ showing the lines of fracture; in the third there may be any degree of compression, and this may show itself in the form of an angular flattening of the apex of the triangle in the lateral view or there may be no angular effect, both the A P. and lateral view showing an opera-hat fracture due to general telescoping of the body.

PREVENTION

In seeking a method of avoiding fractures we must try to determine whether they are due to unnecessarily large dosage, to keeping the patient under unnecessary restraint or in an unfavourable position during the fit, or whether they are an unavoidable consequence of the technique at present employed If the third possibility is the true one, we must look for a way of obtaining a full therapeutic effect with more moderate muscular contractions

It is now thought possible that the therapeutic result is due to temporary anoxæmia, and if we succeed in abolishing the muscular spasm of the diaphragm, intercostal muscles, and possibly the glottis either partially or completely, we shall interfere with the production of anoxæmia, and may render the treatment ineffective If we reduce muscular spasm below the level of the nerves supplying the diaphragm we shall not affect the anoxæmia, but we shall prevent all danger of fracture below this level, and may indirectly lessen the likelihood of fractures elsewhere.

We have, therefore, the following plans for consideration First, we may try to influence the whole muscular system, so as to lessen the violence of the contractions during the fit; secondly, we may concentrate on the muscular system below the level of the diaphragm, or, thirdly, we may apply mechanical methods to modify the muscular activity.

Reduction of general muscular contractions could be produced by those drugs which act on the peripheral

neuromuscular mechanism—namely, curare, conine, gelsemium and sparteine If these drugs are used, however, their effect on respiration will have to be kept in mind.

Reduction of muscular contraction below the diaphragm can be produced by spinal anæsthesia, and this procedure has been used by Hamsa and Bennett (1939) From half to one hour before the injection of cardiazol they give a spinal injection between the 1st and 2nd lumbar vertebræ of 10 mg of pontocaine hydrochloride or 100 mg of procaine hydrochloride dissolved in 4 c cm of cerebrospinal fluid. The anæsthesia, with complete sensory and motor paralysis of all thoracic and lumbar segments, wears off about an hour after the convulsion The fit therefore occurs without contraction of the anæsthetised areas These authors support the importance of cerebral anoxæmia, and therefore prolong the period of apnœa by holding the patient's mouth and nose tightly closed for from half to one minute after the tonic spasm is over

Mechanical methods can be of two kinds The patient can either be placed in a position that will minimise the likelihood of fractures, or he can be so fixed by means of apparatus that movements of the vertebræ are impossible Both these methods are based on the assumption that the injury is due to a crush Polatin and his colleagues have tried placing the patient on his side in a position of acute flexion, but they have treated too few patients in this position to assess its effectiveness Bennett and Fitzpatrick (1939) report that they are considering a modification of the curved Bradford frame, to which the patient can be strapped A possible objection to this method is that although it may protect the vertebræ it may result in extensive tearing of muscular insertions along spinal axis They take the view that until the patient can be protected by apparatus or suitable positioning or by some pharmacological method the treatment must necessarily be suspended But it would be most regrettable if we were to throw over a method of such proved value merely because we have encountered this unexpected and difficult complication

SUMMARY

Vertebral fractures during convulsion therapy have been reported in 40 per cent of cases in the United States, and were found in 5 out of 20 cases treated at Woodside Hospital

The degree of restraint applied during the fit and the dosage employed may be factors in the production of fractures

Muscular contractions might be reduced (*a*) by drugs acting on the neuromuscular junctions, such as curare, (*b*) by spinal anæsthesia, or (*c*) by suitable positioning of the patient or the use of fixative apparatus

Convulsion therapy should not be discarded until methods of preventing fractures have been fully explored

I wish to thank Dr Noel Harris, physician in charge, Woodside Hospital for permission to publish these case records, Mr Philip Wiles for useful criticism, and Dr F G Nicholas and Dr J A Hobson for their coöperation

IMPORTANCE OF BRONCHOSCOPY IN UNRESOLVED PNEUMONIA

BY JOHN E G McGIBBON, M B Lond, D L O
HONORARY AURAL SURGEON AND LARYNGOLOGIST TO THE SOUTHERN BRANCH OF THE ROYAL UNITED LIVERPOOL HOSPITAL

E T BAKER BATES, M D Lpool, M R C P
HONORARY ASSISTANT PHYSICIAN TO THE HOSPITAL, AND

J H MATHER, M.B Lpool, D M R E
HONORARY RADIOLOGIST TO THE HOSPITAL

(*With Illustrations on Plate*)

PNEUMONIA as a rule is a self-limiting disease and it commonly terminates by crisis, which may take place any time between the fifth and ninth days—i e, there is an abrupt fall in the temperature and the pulse and respiration rates, accompanied by a marked improvement in the general condition Termination may take place by lysis—i e, the temperature falls gradually for two or three days with a corresponding gradual improvement in the general condition Occasionally there may be a pseudo-crisis followed by a true crisis or lysis After crisis or lysis there is no appreciable change in the physical signs in the lungs for a few days, when gradual resolution in the affected area takes place Redux crepitations appear, and bronchial breathing becomes less intense and is gradually replaced by normal vesicular breath sounds

Occasionally the temperature and/or clinical signs persist and the condition is referred to as delayed resolution, incomplete resolution, unresolved pneumonia, or, by Scadding (1937), circumscribed non-suppurative pneumonia

Within the past two years a considerable number of valuable contributions have been published on pneumonia—particularly in respect to its atypical forms—but in these there has been brief mention of so-called unresolved pneumonia, and, in spite of the term being in almost daily use, published references to the condition are scanty and evasive It has been said that "few cases diagnosed as unresolved pneumonia are strictly entitled to be placed in that category The term is in common use for cases of pneumonia which pursue an atypical course after the first seven or ten days, and for others which have been erroneously considered to be pneumonia" (Holmes 1936), and it is to these incorrectly diagnosed cases that we wish to call attention, particularly to the help that can be afforded by bronchoscopy in forming a diagnosis and instituting treatment

During the past five years we have examined with the bronchoscope 38 patients incorrectly diagnosed as suffering from unresolved pneumonia, 8 of whom were found to be suffering from bronchial carcinoma, 1 from an extrabronchial tumour of unknown pathology, 2 from impacted non radio-opaque foreign body, 5 from bronchiectasis, 1 from inflammatory stenosis of a bronchus, 2 from lung abscess, 1 from enlarged bronchial glands, and 16 children who exhibited varying degrees of incomplete bronchial obstruction apparently caused by secretion It may be assumed, therefore, that cases of so called unresolved pneumonia may be due either to true delayed resolution or to some other intrathoracic lesion which causes symptoms and clinical and/or radiological signs simulating pneumonia

There is no arbitrary period at which a pneumonia becomes an "unresolved" pneumonia, but if a patient suffering from pneumonia exhibits considerable physical or radiological signs of abnormality in the chest four weeks after the onset of symptoms he may be regarded as suffering from either true unresolved pneumonia or some other complication. It has been our experience that in many cases a differential diagnosis between a true unresolved pneumonia and some other lesion can be made only by direct inspection of the bronchial tree, or by the lapse of time, when possibly irremediable damage has been sustained by the lungs.

INCIDENCE AND DURATION

It has been difficult to collect any accurate figures regarding the frequency and duration of unresolved pneumonia; for, as the term is used so loosely, the available records are not truly comprehensive

Hollinger (1938) states that true delayed resolution occurs in about 2–3 per cent. of cases of lobar pneumonia.

Howard (1936) quotes the following observers' findings in regard to the frequency of this complication of pneumonia: Osler and McCrae, 3–4 per cent; Musser and Norris, 4·1 per cent. in 2548 collected cases; McCrae, 3–7 per cent. in 805 collected cases; and Milne reported that he found at autopsy 10 instances of organisation of exudate in 150 fatal cases of pneumonia—i.e., 6 6 per cent. cases of true unresolved pneumonia.

Kohn and Weiner (1936) surveyed a series of 1000 cases of pneumonia in children and report that 800 of these left hospital alive. Of these 800 survivors 318 were discharged with positive physical signs in their chests, and in 421 radiography revealed some degree of infiltration

Jameson (1929), in a follow-up of 200 cases of pneumonia in children, found that 52 were suffering from severe symptoms of recurrent or chronic pulmonary catarrh—including 14 cases of well-marked fibrosis. There is no doubt that the symptoms of unresolved pneumonia are relatively commoner in children than in adults.

With the kind permission of Dr. W. E. Crosbie, medical superintendent, Dr. B. Dodd has analysed the cases of pneumonia treated in Alder Hey Children's

INCIDENCE OF UNRESOLVED PNEUMONIA IN CHILDREN

Year	Lobar pneumonia	Broncho-pneumonia	Total	Cases diagnosed as unresolved pneumonia
1934	566	530	1096	70
1935	541	469	1010	105
1936	570	441	1011	94
Total	1677	1440	3117	269

Hospital, Liverpool, during 1934–36, and an attempt has been made to follow up the patients who were considered to be suffering from unresolved pneumonia. The accompanying table shows the figures obtained. In this series of 3117 cases of pneumonia 269 (8 6 per cent) remained as unresolved pneumonia. Of these 269 cases 75 resolved before discharge from hospital, 5 patients developed empyema, and 6 died. Of the remaining 183 patients only 71 attended for examination, of whom 47 had no signs, 14 had physical but no radiological signs, and 10 had physical and radiological signs. Therefore, excluding the cases not traced, of 157 cases classified as unresolved pneumonia 122 (78 per cent.) had resolved completely and 35 (22 per cent.) still had evidence of some pulmonary lesion. These figures do not include cases originally diagnosed as unresolved pneumonia and in which a later diagnosis of bronchiectasis or lung abscess was made.

The duration of unresolved pneumonia depends on its cause—i.e, whether it is a true unresolved pneumonia or due to some other lesion.

McCrae followed up 40 cases of unresolved pneumonia, and in all of these there was a complete disappearance of signs and symptoms within twelve weeks.

Kohn and Weiner (1936) attempted to keep under observation 800 children who had suffered from pneumonia, but it was possible only to keep in touch with 66 for nine months or more: 30 cases cleared up completely within five months, the fate of 26 cases is not mentioned, and Kohn (1936) reported on the remaining 10 cases watched over a period of ten years.

He gave a favourable report of these, although 1 patient died, 2 cases resolved after some years, 2 patients had collapsed lower lobes (1 with a cavity), 1 had thickened basal pleura, 1 had a shadow at the hilum and suffered from hæmoptysis off and on for eight years, 2 had physical but no radiological signs after two years, and 1 had physical and radiological signs after four years.

These findings are quoted as probably several of these patients at one time or another were considered to be suffering from unresolved pneumonia.

CLINICAL FINDINGS

For the purpose of these notes and to avoid confusion the definition of terms shown in the following table is employed.

LEGENDS TO ILLUSTRATIVE PLATE

MR DIX AND DR. EVANS

FIG. X.—Excretion pyelogram at the 28th week of pregnancy. Normal dilatation of ureters above pelvic brim. The ureters below the pelvic brim were not dilated.

FIG XI.—Excretion pyelogram at the 30th week of pregnancy in a patient who had pyelitis on the right side.

FIG. XII.—Excretion pyelogram on the 13th day after parturition in a patient (case 5) who had had pyelitis.

FIG. XIII.—Excretion pyelogram in the same patient as in fig XII (case 5) two years later, showing return to normal condition.

FIG. XIV.—Excretion pyelogram two years after a pregnancy in which there had been pyelitis on the right side. There was still a urinary infection, and subinvolution of the right ureter is well shown

Airlessness of lungs
Developmental or congenital (atelectasis)
Exudative (pneumonia, pneumonitis, œdema)
Compression collapse (pleural effusion, pneumothorax)
Absorption collapse massive or segmental collapse (extrinsic or intrinsic bronchial obstruction)
With distal exudate (drowned lung † pneumonia, † pneumonitis)
Without distal exudate (so-called triangular shadows)

Clinically it is possible to divide cases diagnosed as unresolved pneumonia in our series roughly into four groups —

(1) Cases simulating true pneumonia in which the expected crisis or lysis did not take place and constitutional and local signs and symptoms persisted

(2) Cases simulating true pneumonia in which crisis or lysis took place but after a varying interval there was a recrudescence of the general and local signs and symptoms.

(3) Cases simulating true pneumonia which apparently terminated by crisis or lysis but in which local symptoms and signs persisted without any manifest constitutional disturbance

(4) Ambulatory cases presenting themselves with a variety of pulmonary complaints and manifesting local signs and symptoms of unresolved pneumonia without any history of antecedent acute pulmonary disease

In groups 1 and 2 the picture has been that of an acute or subacute respiratory disease with cough, sputum, and evidence of general toxæmia The symptoms depended to some extent on the exact situation of the lesion in relation to surrounding structures When it was situated in or near a main bronchus, irritating cough and hæmoptysis were common symptoms At first the cough was unproductive, but later the sputum became copious and purulent, and its odour varied with the infecting organisms If the lesion was situated near the surface of the lung, pain on breathing was experienced owing to pleural involvement In other cases there was a much more striking general reaction, with high fever and paroxysmal cough, without sputum at first, but later with a considerable amount of sputum streaked with blood and occasionally offensive In groups 3 and 4 the symptoms were those of a mild general toxæmia There were no serious respiratory symptoms or signs on clinical examination, and often the condition was recognised only by radiography of the chest

Clinical examination yielded very divergent results, for the physical signs varied with the situation and size of the lesion Partial suppression of breath sounds, associated with dullness and occasional crepitations, was found as often as bronchial breathing in the early stages of consolidation caused by incomplete bronchial occlusion When the lesion was situated deeply in the lung tissue there were no physical signs, but when the lesion was more superficial there were restriction of movement on the affected side, impairment of the percussion note, bronchial breathing, and crepitations Vocal vibration was usually increased, and the voice sounds were bronchial Sometimes the breath sounds were absent and the distinction between consolidation, pleural effusion, and collapse was very difficult to make by clinical examination, for there was usually no displacement of the heart unless there was frank lobar collapse The important physical sign was the absence of breath sounds, for as a rule there were no added sounds, although crepitations and rhonchi were sometimes heard It is essential, therefore, to ascertain if there is deficient entry of air into the affected area of lung, such a discovery arising late in the course of a pneumonia should lead to a reconsideration of the diagnosis

The sputum was always examined for tubercle bacilli as a routine measure on three occasions at least during the acute phase, and the examination was repeated if the clinical course did not go as expected, Empyema was anticipated and excluded by radiography, and any suspected area was explored with a needle

The cases in this series which presented the greatest diagnostic difficulties on clinical and radiological examination were those with incomplete collapse, especially when the lesion was retrocardiac Cases conform to the classical description of lobar pneumonia less often than formerly, hence it has been said by the older clinicians that the type of pneumonia has changed The physical signs of many of the atypical pneumonias are so alike as to render differentiation at the bedside virtually impossible Hitherto radiography has afforded the main distinguishing features, and attempts to classify these similar clinical states of varying ætiology have been almost all radiological But, although radiography has clarified the pathology of many pulmonary conditions the findings should not be regarded as final They are only to be considered in conjunction with all other aspects of the case and not to the exclusion of further methods of examination

In this respect so-called "primary" pneumonitis (Gill 1938) is so far merely a radiological conception and is probably due, as Beaumont (Gill 1938) has

suggested, to a partial obstruction of the bronchioles with mucopurulent exudate, but its pathology meanwhile is conjectural. It appears to us to correspond to the benign form of pneumonia which sometimes occurs after removal of tonsils; for, as Burrell (1938) has pointed out, the word "pneumonitis" has the same meaning as pneumonia—namely, an inflammation in the lung. Maxwell (1938), in a more recent paper, has emphasised the importance of the recognition of primary pneumonitis as a separate clinical entity and suggests that the term should be confined to cases with good local and general resistance in which the disease runs a benign course.

"Secondary" pneumonitis (Gill 1938) or "secondary" pneumonia (Burrell 1938) is a definite entity and is the local reaction of the lung in response to one of many ætiological factors, usually a low-grade inflammation affecting the alveoli and associated with exudation. A photomicrograph of "secondary" pneumonitis is reproduced in fig. I from a case of inhaled foreign body, and it shows the similarity of the histological picture to that of pneumonia.

A similar criticism can be applied to the clinical term "damaged lung," which was originally introduced by Riviere (1923), and round which the literature has grown to such an extent that the term "damaged lung" is recognised more or less as a diagnosis. Such terms are generalisations and give no hint of the exact causation or pathology of the lesion.

RADIOLOGICAL OBSERVATIONS

In resolving pneumonia radiography shows mottled shadowing in one or more lobes, occasionally accompanied by enlarged root-shadows on the affected side, but without any appreciable collapse of the lung (fig II on plate) It is advisable, whenever possible, to radiograph every patient recovering from pneumonia; and, if the symptoms or clinical signs persist, the patient must be radiographed again after an interval of seven to ten days When the shadowing shows no change or has increased, some other lesion should be suspected and further methods of examination should be instituted without delay. If only a single radiological examination is carried out, it is impossible to distinguish between a resolving pneumonia, a true unresolved pneumonia, or pneumonitis secondary to incomplete bronchial stenosis (caused by secretion, non-opaque foreign body, or simple or malignant new growth) The X-ray appearances of resolving pneumonia may be simulated by pulmonary tuberculosis, epituberculosis, and occasionally by bronchiectasis, but in the last condition there is usually some evidence pointing to collapse of the lobe involved—as mentioned earlier, collapse is not a feature of resolving pneumonia.

FIG I—Photomicrograph of lung in pneumonitis due to impaction of a foreign body

PATHOLOGICAL CONSIDERATIONS

In our series of cases the pathology has been that of interference with bronchial drainage, associated with secondary changes distal to the obstruction. Plugs of secretion, foreign bodies, bronchial stenosis, neoplasm, and pressure of tumours from without have caused the obstruction. All grades of secondary lesions have been found, and these secondary manifestations have varied with the rapidity and cause of the obstruction and with the virulence of the organisms present. The clinical signs and symptoms and the immediate gravity of the illness have depended on the secondary complications, which as a rule completely overshadowed and obscured the primary cause Rapid obstruction produced partial collapse, which was either lobar or segmental, according to the size of the obstructed bronchus; or, if segmental, neighbouring affected segments became confluent with lobar collapse. If the obstruction took place more slowly, so-called "drowned lung" was brought about.

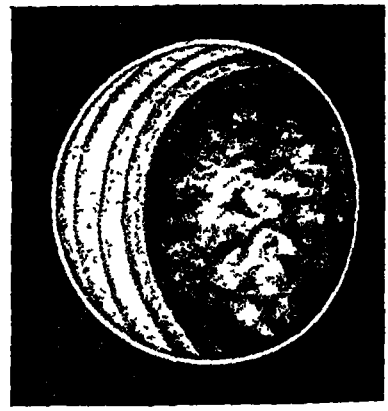

FIG IV—Granulation-tissue filling right lower bronchus, as seen on bronchoscopy (same case as figs. III and VI on plate).

CAUSES OF OBSTRUCTION

Viscid secretion was the commonest cause of bronchial obstruction in our series—18 cases out of 38—and the obstruction was usually in the bronchi of the middle or lower lobes. Although bronchial obstruction due to retained secretion was described as an entity nearly a hundred years ago (Thomas 1938), interest in it did not revive until Pasteur (1908) published his papers on pulmonary collapse sixty years later. The latter, however, did not consider that bronchial obstruction due to secretion was the cause of collapse, and it is only within the past ten years that the frequency of secretion as an obstructing agent, its easy removal, and the gratifying results thereby obtained have become generally recognised The rôle of secretion as an obstructive agent has been emphasised, among others, by the following workers

Lee and Tucker (1928) showed experimentally that "massive collapse" was due to bronchial obstruction by secretion, and in conjunction with Ravdin and Pendergrass (1928) they produced collapse of the lungs in dogs by inserting into their bronchi plugs of mucus which had been obtained from those of human patients

Coryllos and Birnbaum (1933) drew attention to the importance of secretion as a cause of bronchial obstruction and noted the extreme viscosity of pneumococcal sputum, which contains fibrin and coagulates very rapidly They went so far as to define lobar pneumonia as a complication of a pneumococcal bronchitis, caused by bronchial obstruction by exudate infected with virulent pneumococci.

Burrell (1938) also suggested that pneumonia might be caused by plugs of secretion in the bronchi Gunn (1938) has described the difficulty of infecting laboratory animals by merely spraying broth cultures of pneumococci into the bronchi, whereas, if virulent cultures mixed with mucus, sterile mucin, or viscus starch-paste were injected well down into the bronchi, pneumonia resulted in almost all the cases

Clinical support of this theory of the pathology of pneumonia is borne out by the observations of Corylios (1920), who aspirated bronchoscopically 9 cases of pneumonia with beneficial results Tallerman and Jupe (1929) and other observers have described mediastinal shift to the affected side sometimes seen radiologically in the early stages of the disease

Erwin and McGill (1938) observed 2 cases of pneumonia with definite clinical signs of a blocked bronchus, and Telling and Oliver (1938) have recorded notes of a case of pneumonia with massive collapse These last observers point out that complete collapse of a single lobe in lobar pneumonia is commoner than is supposed, and they refer to reports of 62 cases with complete lobar collapse and 10 cases with massive collapse of the whole lung

Anspach (1934) described 50 cases of pulmonary collapse in children, of which he had investigated all clinically and radiologically and several at autopsy In the latter he found thick tenacious exudate filling the smaller bronchi De Brun and Gerlings (1936) also have published a very full description of collapse of the lung in children due to occlusive secretion and Maxwell (1937) has described massive collapse of the lung in patients with bronchitis and asthma—one patient was cured by bronchoscopic aspiration of secretion, another coughed up a large plug of mucus with complete relief from symptoms, and the third was cured by breathing exercises

That this type of bronchial obstruction is common in children is explained by the small lumen of their bronchi, feeble cough, and disproportionately small larynx, which hamper removal of secretion, and it can be appreciated readily that a very slight degree of mucosal swelling of the small bronchial divisions of a child will contribute considerably towards any obstruction Incomplete collapse of a large part of a lung can occur therefore in young children from very slight causes, and so, when signs of consolidation are found in a young child, the above mentioned possibilities must be considered

FIG VII—Same case Photograph of bronchiectatic lung removed by lobectomy

It is now recognised that this kind of obstruction is a precursor of bronchiectasis, and that the permanence and extent of the damage brought about is proportional to the length of time the bronchus remains occluded We have observed the supervention of undoubted bronchiectasis within a few weeks, Warner and Graham (1933) have reported the development of this complication within six weeks of bronchial obstruction, Boyd (1935) within fourteen days, de Brun and Gerlings (1936) within seven weeks, and Hollinger (1938), in a description of 3 cases of so-called unresolved pneumonia due to bronchial obstruction by plugs of secretion, saw bronchiectasis become manifest in two months

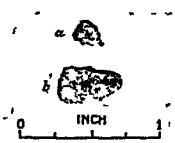

FIG V—Same case Photograph of two pieces of bone (life size) removed from left lower bronchus

A collapsed lobe with its relaxed bronchi may simulate bronchiectasis by contrast radiography with apparent *recovery from the condition* on re expansion of the lobe, as has been pointed out by Chandler (1937), but there is no doubt that recovery may take place in early cases of true bronchiectasis, after restoration of the patency of the bronchus We have seen this take place, Findlay (1935) drew attention to it when discussing bronchiectasis in children, and Jennings (1937) has reported a case which recovered

Inhaled foreign bodies which are radiologically non opaque were found in 2 of our cases and gave rise to the picture of so called unresolved pneumonia, owing to the partial bronchial obstruction produced with secondary pneumonitis and pulmonary suppuration It is our impression that the entrance of foreign bodies into the bronchi is not so rare as current teaching would have us believe The effects of a foreign body in the tracheobronchial tree are sufficiently well known and do not need elaboration The obvious cases are dealt with promptly by the laryngologist, but it is in the obscure cases presenting only signs of pulmonary infection that the true cause is overlooked It might be supposed that the entry of a foreign body into a bronchus could hardly escape notice. This, however, is by no means true; and, if death does not quickly supervene from pneumonia or gangrene of the lung, the patients may seek advice because of symptoms suggesting the presence of some lesion in the chest, which is in reality secondary to bronchial obstruction, by a foreign body As a general rule the lower down the respiratory tract the foreign body goes, the less the irritation and distress at the time, although this depends also on the nature and mobility of the inhaled object

The early result caused by the foreign body may be either obstructive emphysema or collapse of part or the whole of the lung These conditions should be readily recognised clinically and on radiography If, however, the bronchus is not completely occluded, a secondary pneumonitis will develop which eventually may be regarded as an unresolved pneumonia *Later changes are those due to suppuration* of the lung—bronchiectasis, abscess, and gangrene One case from our series is described below and is illustrated serially in figs III and VI on plate and IV, V, and VII in text

On Dec 23, 1936, a woman of 30 complained of cough and expectoration of seven months' duration with recurrent "influenzal" attacks Some limitation of movement and crepitations at the right base were evident On the 29th radiography showed that "appearances point to consolidation—probably unresolved pneumonia of right middle and lower lobes No evidence of tuberculosis" (fig III on plate) On Jan 25, 1937, radiography after Lipiodol showed "normal lipiodol" On the 26th bronchoscopy revealed a mass of granulation tissue

filling the right lower bronchus (fig. IV), from which a small piece of bone was removed (fig. V).

The patient's symptoms became more severe. There was much cough with copious mucopurulent sputum, and clubbing of her fingers developed. On May 31, 1937, bronchoscopy showed the granulations still present, and a second and larger piece of bone was removed (fig. V). Subsequently her general condition improved, but the cough persisted with purulent expectoration and occasional hæmoptysis. On Dec 20, 1937, bronchoscopy showed that the granulations had entirely disappeared from the right lower bronchus, but pus was welling up from the basic bronchi. On the 21st radiography after lipiodol showed "saccular bronchiectasis of right lower lobe" (fig. VI on plate). On March 9, 1938, lobectomy was performed by Mr. J. T. Morrison (fig. VII). The patient made a good recovery and has remained well since.

Incomplete bronchial stenosis was found in 1 case. Bronchostenosis is considered to be almost always secondary to impaction of a foreign body, although we consider that we have examined at least one patient in whom a congenital bronchostenosis was present with a small localised distal bronchiectasis. Hollinger (1938) has described a case of so-called unresolved pneumonia which exhibited bronchial stenosis, and Davidson and Freedman (1933) have reported stenosis of the left main bronchus in a woman, aged 43, who gave a history of acute lung disease 25 years previously. Our case was that of a child with stenosis of the right lower bronchus after inflammation.

Bronchial neoplasm is a common cause of bronchial obstruction, and, as Burrell (1938) has pointed out, "the first manifestation may be an acute illness called, and rightly called, pneumonia" In the early stages of bronchial carcinoma there may be no physical or radiological signs of disease. This has been emphasised by two of us in a recent paper (McGibbon and Baker-Bates 1937). Sooner or later, however, bronchial occlusion, transient or permanent, takes place, and some degree of secondary pneumonitis or pulmonary suppuration always occurs distal to the block This accounts for the diagnosis of unresolved pneumonia which may be made radiologically in the early phases of the disease There were 8 cases of bronchial carcinoma incorrectly diagnosed as unresolved pneumonia in our series

Pressure from without the bronchus may be due to many causes, but in our series it has been due to neoplasm or to tuberculous glands Anspach (1934) has described bronchial obstruction caused by cardiac enlargement and has suggested that it might occur also in Pott's disease or aortic aneurysm Brook, Cann, and Dickinson (1937) also have described cases due to pressure exerted by tuberculous glands Such pressure from without produces partial or complete bronchial obstruction, and the end-results are similar to those due to intrinsic causes

PROGNOSIS

The prognosis in our series nearly always has been serious, but it varied from case to case, and no general rules can be laid down. No patient suffering from unresolved pneumonia with stationary clinical or radiological signs should be treated expectantly; bronchoscopy should be undertaken, for irremediable damage may otherwise take place Although the lung is normally one of the best-drained organs in the body, once bronchial obstruction develops it is one of the worst drained, and it has been shown repeatedly that obstruction, complete or incomplete, leads to either pulmonary suppuration—abscess or gangrene—or collapse with an associated bronchiectasis. It is of paramount importance, therefore, to attempt removal of any bronchial obstruction, from whatever cause, at the earliest opportunity, to restore the patency of the bronchus and re-aeration of the lung before these secondary effects supervene.

SUMMARY

(1) A series of cases is reviewed in which the clinical and radiological features suggested unresolved pneumonia but the common lesion was bronchial obstruction

(2) The importance of early bronchoscopy in conjunction with other methods of investigation is emphasised

(3) The causes of obstruction were plugs of secretion, foreign bodies, bronchial stenosis, new growths, and extrabronchial pressure

(4) The common secondary results of bronchial obstruction are pneumonitis, collapse, bronchiectasis, lung abscess, and gangrene. These may be associated with various diseases of the lung or bronchi, and it is important to realise that they are due to other pathological conditions; they should not be regarded as independent diseases

(5) All patients who have had pneumonia and have any symptoms three or four weeks after the onset should be radiographed If a diagnosis of unresolved pneumonia, resolving pneumonia, delayed resolution, or incompletely resolved pneumonia is made, radiography should be repeated after ten to fourteen days If there is then no appreciable change, or if the radiological signs are more obvious, broncho scopy should be carried out without delay.

(6) Ambulatory cases—group 4 in our series—presenting radiological signs should be radiographed again and treated in a similar manner.

(7) It is only after taking serial radiograms that the radiologist can be dogmatic about the diagnosis of true resolving pneumonia

(8) The cases which are diagnosed radiologically as "unresolved" or "resolving" pneumonia are those in which there is partial bronchial stenosis with secondary changes distal to it. If there is complete stenosis, there will be evidence of segmental or lobar collapse, which will produce an entirely different radiogram from those in unresolved pneumonia.

(9) The age of the patient must be considered when a diagnosis is sought In children and young adults true unresolved pneumonia and incomplete bronchial obstruction due to secretion or foreign body are the common causes of symptoms and signs. In adults bronchial carcinoma is the commonest finding

(10) In the cases described above the pathological changes have been secondary to partial bronchial occlusion, and true pneumonia also may be due to bronchial obstruction. The pathological states found in unresolved pneumonia and true pneumonia may thus be produced by similar mechanical means, and the end-results may differ only inasmuch as the obstructing agents vary.

SURGICAL CONSERVATION OF HEARING

By Alexis Tumarkin, M B Lpool, F R C S E, D L O
AURIST TO BOOTLE HOSPITAL

(With Illustrations on Plate)

It has been well said that chronic aural suppuration is a reproach to medical science Organised coöperation between otologist, medical practitioner, and medical officer of health will undoubtedly abolish this menacing disease someday Until that day arrives, however, otologists will continue to find most of their time taken up with "chronic ears" The treatment of chronic aural suppuration has a twofold purpose—namely, to preserve hearing and to preserve life, but unfortunately the surgeon is not always able to reconcile the conflicting demands made on him Of course, in a considerable proportion of cases, conservative treatment will cure the inflammation, and so remove at one stroke both the threat to hearing and the threat to life *

It is in the remaining cases that the surgeon must make the difficult decision whether to operate or not Only too often in his anxiety to avert any potential intracranial complications the surgeon is tempted to sacrifice the hearing quite ruthlessly It has been maintained that in certain cases the radical mastoid operation improves hearing This is true, but only of patients whose hearing was grossly impaired beforehand Even so, the improvement is rarely such as to make the ear a really useful one

Certainly in the type of case which I describe below as chronic perforating epitympanitis, in which the hearing is good beforehand, the classical mastoidectomy will have a disastrous effect on hearing An American authority writes, 'Chronic suppurative otitis media usually begins in childhood When prolonged into adult life, permanent deafness always results, and operations are then of little or no value in restoration of hearing" (Fowler 1937)

If this gloomy account were accepted as comprehensive and final, we should have to admit that surgery has little or no place in the conservation of hearing I hope to show in this article that the position is quite different We can hold out to many of these sufferers a promise of arresting that inexorable descent into the hell of deafness, and indeed can often restore hearing which apparently had been permanently lost I include, for instance, in my present list several patients who hear now better than they have done since childhood One man indeed now depends for his livelihood on an ear which for twenty years he regarded as useless

The fact is that the classical radical mastoidectomy was designed to deal with pan otitis—a pathological entity which emerged so to speak with the dawn of otology Chronic otorrhœa as we see it today is rarely due to pan otitis, it is due to chronic epitympanitis, for which, as I have already said, the classical operation is a disastrous mistake

Let us recall the surgical anatomy of the ear We may regard the middle ear as a box of which the wall facing us is partly constituted by the tympanic membrane (fig I) It is vital for the present argument to remember that the upper part of this wall is bone

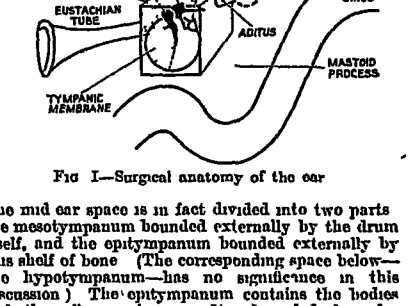

FIG I—Surgical anatomy of the ear

The mid ear space is in fact divided into two parts the mesotympanum bounded externally by the drum itself, and the epitympanum bounded externally by this shelf of bone (The corresponding space below—the hypotympanum—has no significance in this discussion) The epitympanum contains the bodies of both malleus and incus It is bounded above by the tegmen tympani separating it from the meninges, but posteriorly it communicates by a narrow corridor—the aditus—with the mastoid antrum The latter is a comparatively large cavity in the body of the mastoid bone, while radiating from it in all directions are galleries of air cells giving the typical pneumatised appearance seen in fig IIa on plate

PAN OTITIS AND PERFORATING EPITYMPANITIS

In pan otitis any or all of the following conditions may be found

(1) The drum is perforated and may indeed be completely destroyed

(2) Polyps or masses of exuberant granulation tissue spring from patches of unhealthy bone

(3) The ossicles may be carious, and in some cases completely destroyed

(4) The mastoid antrum and adjoining air cells may be occupied by unhealthy tissue or mucopurulent discharge

(5) Fistulæ may erode into adjacent vital structures—the brain, lateral sinus, labyrinth, facial nerve, and so on

This type of advanced pan otitis was comparatively common years ago, and the earlier otologists quite rightly dealt with it by means of the radical mastoid operation This aimed at eradicating all unhealthy tissue, and by converting the whole space into a single cavity it ensured adequate drainage, so averting the dreaded intracranial complications

* In a small proportion of cases curing the suppuration temporarily diminishes hearing This can by no means be regarded as justification for neglecting the discharging ear Such cases are the exception and furthermore the suppurating ear will surely deteriorate more rapidly than the dry ear so that the end result is invariably worse in untreated cases

Within recent years, the picture presented by chronic otorrhœa has changed considerably. Widespread adoption of preventive measures and the all-round improvement in conservative lines of treatment have almost abolished the type of "chronic ear" described above. This subsidence of chronic pan-otitis however has allowed a totally different type of infected ear to emerge and assume its proper importance I refer to chronic perforating epitympanitis This condition presents the following remarkable features.

(1) The tympanic membrane may be intact except for a tiny perforation in Shrapnell's membrane or in the post superior quadrant (fig. III). Usually this perforation is occupied (see fig. IV) by a polyp which arises from the diseased area in the attic.

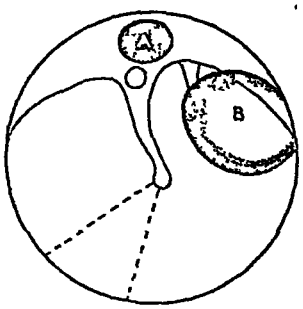

FIG III—Tympanic membrane showing typical situations of perforations in chronic epitympanitis A, in Shrapnell's membrane, B, in posterior superior quadrant.

(2) The ossicles may be quite healthy even in cases of twenty years' standing

(3) The structure of the mastoid bone is quite different from the pneumatised type of fig. IIa. Usually there are no air cells whatsoever, and the bone is diploetic just like any other cranial bone (fig. IIb on plate) or it is a solid mass of compact bone (fig. IIc on plate). This fact is of vital importance to the present argument. It is true that long-standing suppuration in the centre of such a bone can produce osteosclerosis, caries, and even massive necrosis; nevertheless, in the great majority of cases none of these occurs. Such a mastoid bone, like the ossicles and the main part of the tympanic membrane, is quite capable of remaining healthy during ten or twenty years of otorrhœa.

(4) Because of the above factors the hearing is often remarkably good.

(5) Despite its apparently benign features, this condition resists most obstinately the standard conservative measures mainly because the minute perforation effectively prevents the application of dressings to the inflamed lining of the epitympanum.

(6) In those unfortunate cases in which extension to adjacent structures does take place, the process is liable to advance so insidiously that almost the first warnings of its presence may be a fulminating meningitis or sinus thrombosis.

These essential peculiarities of this epitympanitis have never really received adequate recognition, and many surgeons still adhere to the deplorable practice of exenterating the delicate (and often quite healthy) middle-ear structures in their routine performance of radical mastoidectomies for intractable otorrhœa. Obviously in such cases there will be a marked depreciation in hearing. Dan McKenzie (1931), referring to this problem and its solution, wrote:

"Treatment is suggested, namely, in the case of disease limited to this small area and not getting well to remove the thin plate of bone by punch forceps from the meatus so as to provide free exit for the contained debris. As the cholesteatomatous lining may be left in situ, if other symptoms which indicate wider infection are absent, the mastoid route of access is unnecessary. Consideration of this aspect of our subject, however, raises a wider question. In the past when dealing with cholesteatoma the attention of the surgeon has been focused upon the supposed cause of the cholesteatoma, the suppuration of the middle ear, and his efforts have been applied to getting rid of this disease. But, as we have shown, middle-ear disease may be entirely absent. How many hearing ears have been destroyed by this misconception?"

Let us recall that the mesotympanic structures are healthy—i e, drum and ossicles. The mastoid bone itself is healthy. All we have really to deal with is the focus in the epitympanum, and even this is usually a mere mucosal infection, rather than a true osteitis In fig. IV I have drawn a longitudinal section of the ear, showing this focus of infection, inadequately draining through a small perforation in Shrapnell's membrane The perforation, in addition, is blocked by a polyp. The solution to our problem becomes obvious at once As McKenzie said, all we need do is provide drainage by removing the "plate of bone"—i e, the outer wall of the attic.

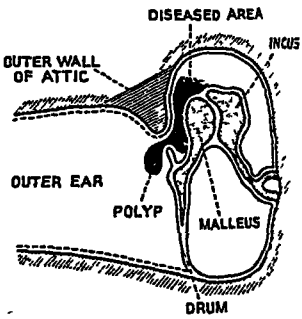

FIG IV—Chronic epitympanitis showing how removal of the outer attic wall affords room for drainage and the application of medicaments to the diseased area in the epitympanum.

TRANSMEATAL ATTICOTOMY

Why then did no one carry out the operation? Presumably because surgeons were fixed in their habit of approaching the middle-ear structures via the mastoid. They did in fact compromise by inventing the transmastoid atticotomy. In this latter operation the mastoid is opened and exenterated solely as a means of approaching and draining the epitympanum The ossicles and drum, wherever possible, are left intact. Admittedly a step in the right direction, this operation still has many disadvantages in comparison with the transmeatal approach. We may note the following.

It entails a postaural incision with its sutures, ligatures, possible stitch abscesses, and so on.

It produces a large raw bone cavity inadequately lined by skin flaps which are only too liable to become gangrenous. In contrast with this the meatal operation leaves intact the mucosal lining of the bone which, although chronically inflamed, is quite capable of healing perfectly if properly drained. There is adequate healthy skin to cover the small raw edge of bone. In some cases the final result is amazing; it would be impossible to recognise that an operation had been performed.

There is no comparison between the magnitude of the two operations. The one is a major operation lasting 1–1½ hours under a general anæsthetic and entailing two or three weeks in hospital; the other is a minor procedure usually performed under a local anæsthesia and lasting about 30 min. The patient is out of bed the next day and can leave hospital immediately, though I usually keep him in under observation for two or three days.

The reader may well inquire what compensating disadvantages must otologists have visualised. What difficulties, imaginary or real, deterred a generation of surgeons from attempting this operation? The question is partly answered by the following opinion of a well-known American surgeon (Shambaugh 1937)

"This operation, similar to ossiculectomy with removal of the outer attic wall through the meatus, has the same disadvantages: limited visibility,

limited accessibility and therefore increased danger of facial-nerve injury or stapes luxation. The post-aural route has no disadvantages to compare with the increased hazard of the canal route."

My answer to this is an emphatic denial. Admittedly the operation is not one for the casual otologist, but neither is any other procedure that aims not only at curing the disease but also at conserving the hearing. In conscientious and careful hands transmeatal atticotomy can be performed with the precision of a watchmaker. The ossicles, drum, and the region of the semicircular canal and facial nerve are under close supervision all the time and the clear cut bloodless field (produced by local anæsthesia) permits delicate manipulations which would be quite impossible in the blood-filled depths of an ordinary mastoidectomy cavity. On the Continent, and, I believe, in Russia, the operation is gradually gaining recognition, having been advocated by a small band of enthusiasts for some years (Kecht 1936, Thies 1933, and Trampnau 1936).

It is not possible in an article of general interest to discuss details of technique. Suffice to say that under local anæsthesia a small skin flap is turned down from the deep part of the osseous meatus just where it abuts on the post-superior quadrant of the drum. The bone thus exposed is none other than the outer wall of the attic. It is carefully chiselled away and then the skin flap replaced and tucked down over the raw bone edge. No dressings are required but the usual supervision of the tiny cavity is maintained subsequently till healing is complete. This after-treatment is of supreme importance. The operation merely gives the surgeon access to the delicate mucoperiosteal lining of the attic, ulcerated by years of chronic inflammation. The recuperative power of this lining is trivial compared to, say, skin or mucous membrane. To leave this work to the unskilled hands of nurse, house-surgeon, or even clinical assistant is to invite failure. Unless a surgeon intends to supervise these cases personally, he had better not undertake transmeatal atticotomy.

Now, I am not going to maintain that this operation will always result in a dry ear. I could point out that a depressing proportion of classical mastoidectomies are failures from that point of view also. It is not a question of contrasting the merits of two alternative operations, but rather of deciding on the indication and function of two entirely different procedures. I submit that for "chronic perforating epitympanitis" the transmastoid operation is wrong, and the transmeatal is right. For chronic pan otitis the transmastoid is probably inevitable, but if conservation of function is desperately important, the surgeon may begin with a meatal operation provided he is prepared to do a subsequent mastoid exploration if otorrhœa persists. Between the two extremes there are many intermediate cases in which opinion might vary. My own preference will always be for the meatal operation. It only remains to give clinical details of illustrative cases.

RESULTS

First, let us show that transmeatal atticotomy can cure chronic otorrhœa which has defied intensive conservative treatment. It should be emphasised that in no case was the operation performed until it was obvious that a prolonged and intensive conservative treatment had failed. A minimum of two months was imposed, several cases were treated for six months, one for over a year, and one actually for nearly four years. Patients were seen weekly and even oftener if necessary. Ionisation, iodised boric powder, bipolar electrolysis, attic lavages with carbon tetrachloride, short wave diathermy, and other non-surgical methods were used, and it can be rightly claimed that these cases—apart from operation—were incurable and so doomed to progressive deafness. In several cases the hearing was at a very low level, the otorrhœa having been present for as long as twenty years.

Out of 17 such operations which I have performed during the last year, 13 are quite dry and 2 more recent cases are almost dry, 1 case had a further transmastoid exploration and is now dry, 1 case has continued to suppurate and must therefore be considered a candidate for a transmastoid operation. It is manifest that in properly chosen cases of chronic otorrhœa, a high percentage of cures is obtainable by this operation.

What of the effect on the hearing? This, after all, is the point which concerns us most. In only one case was the hearing impaired as a result of the operation. This is due to the fact that I unfortunately dislocated the incus and had to remove it. One patient complained of some loss of hearing after preliminary amputation of a polyp, but even in this case, the subsequent atticotomy restored his auditory acuity to its previous level. Three patients said that their hearing was not improved, but that it had certainly not deteriorated. We must remember that a dry ear is less liable to progressive deterioration than a suppurating ear. It is for that reason that I have spoken of the surgical "conservation" of hearing.

Surely it is not unreasonable to claim that these patients have been preserved from deafness. In the remaining 13 cases it is justifiable to claim much more than that. Everyone of this group achieved a

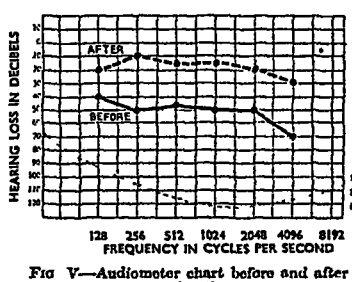

FIG V.—Audiometer chart before and after transmeatal atticotomy.

definite improvement in auditory acuity, and indeed in some of them the change was most dramatic. The audiogram shown in fig. V is typical, but for less technically minded readers it may be more satisfactory to read what the patients themselves have to say. For this purpose I sent out a questionary simply asking patients to describe the conditions of their hearing compared to what it was previously, and to state how they arrived at their conclusions. The following remarks are extracted from some of their replies:

(1) "There is a vast improvement in the ear. Many people who have known me for a number of years do not have to shout now. I can hear perfectly over the telephone." (This man's other ear was profoundly deaf.)

(2) "I am pleased to say the hearing in that ear (the right) was almost normal by April, 1939, and has

remained so to date." (This man had regarded his right ear as useless and merely attended because the otorrhœa of about twenty years' standing was becoming too troublesome.)

(3) " . . . for instance, I received a message by the telephone early this morning. A year ago this was a dead instrument to me. I now hear the sound of boiling water, and of our dog sleeping, &c., &c., in fact, my hearing is almost 100 per cent. perfect."

(4) " Willie was deaf for a few years before you took him for treatment. His hearing is now so much better that he can hear me when I am speaking quite low. He can also hear the least sound."

(5) " Before treatment I was quite deaf in that ear. Now I can hear a small watch ticking at 12 in., and a clock at 5 or 6 ft. away."

(6) " My ear is alright and I can hear quite well now. The only test I can tell you is that I have no pain now, and I can hear when anyone speaks. I do not have to ask them to repeat themselves."

(7) " Before you healed my ears, if I lay down for any length of time I went quite deaf. . . I nearly had to give it (my work) up as I could not hear the orders I myself know I am 100 per cent. better now, also I have been told so by others."

It would perhaps be even more convincing to see the changed facies, mentality, and even physique of some of these patients who have so dramatically recovered their hearing. I am quite certain that no surgeon who has once seen his work rewarded by such results would dream of doing a radical mastoid in chronic perforating epitympanitis. McKenzie was quite right when he said years ago that the correct operation was " to remove the thin plate of bone via the meatus—the mastoid route was quite unnecessary." I believe the present series of cases gives ample proof that he was not a false prophet

SUMMARY

Chronic perforating epitympanitis produces a type of otorrhœa which is frequently benign in that it may persist for many years without serious involvement of drum ossicles or mastoid bone

Because of its chronicity, and the definite (although infrequent) occurrence of intracranial complications, this condition has been regarded as an indication for a radical mastoid operation. This attitude has undoubtedly resulted in much unnecessary suffering and deafness

The alternative operation of transmeatal atticotomy has apparently never been performed in England This operation, though requiring considerable " skill," is a minor procedure from the patient's point of view. It takes about half an hour under local anæsthesia and the patient can leave hospital on the second or third day There is no external incision, no sutures or ligatures are required, and after-treatment, although technical, is reduced to a minimum.

In the presence of gross disease of ossicles and drum there is little to gain from this operation, and in chronic suppurative mastoiditis it is definitely contra-indicated.

Most cases of chronic otorrhœa in adult life, and many in childhood, are due to chronic epitympanitis. Generalised tympano-mastoid disease—i e , pan-otitis —may have been common years ago, but is comparatively rare now.

Cases are quoted to show that not only can the operation cure suppuration and thereby conserve hearing, but in favourable cases it may actually restore hearing which had been lost since childhood.

Surgeons in the past may have avoided this operation because of its technical difficulties, real and imaginary, but more important is the failure to distinguish between chronic epitympanitis and chronic pan-otitis.

In experienced hands complications should be much rarer than in the radical mastoid operation. There have been no complications in the present series

A dry ear can be obtained in a high proportion of cases and hearing is improved to a surprising extent.

ANGINA IN PERNICIOUS ANÆMIA

WITH ELECTROCARDIOGRAPHIC CHANGES AND ABDOMINAL ANEURYSM

BY SIDNEY VATCHER, M.D. Camb.
MEDICAL OFFICER, MINISTRY OF PENSIONS

(With Illustrations on Plate)

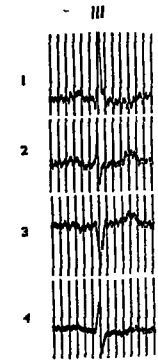
THE case here described showed two interesting features First, symptoms of angina pectoris were associated with pernicious anæmia and with electrocardiographic changes which disappeared after liver therapy Secondly, this was a good example of an abdominal aneurysm, a rare condition, confirmed by radiography, the outline of the aneurysm being extremely well shown owing to the presence of calcification.

CASE-RECORD

A nurse, aged 63, who had served in the late war, had complained of indefinite abdominal symptoms, chiefly constipation and abdominal pains, since 1918. In August, 1937, she had tachycardia on slight exertion, and was kept in bed for the next three months; on getting up she began to have precordial pains on exertion radiating down the left arm into the fingers. At the same time her abdominal pains became worse and vomiting set in She also complained of sore tongue.

On examination in April, 1938, she was thin and pale. Clinically the heart and lungs were normal and the tongue appeared normal. A pulsating mass was felt in the region of the lower abdominal aorta. A radiogram of the abdomen showed a calcified aneurysm of the abdominal aorta about 2 in. by 2¼ in., extending to the left of the spine at the level of the 4th and 5th lumbar vertebræ (figs I and II on plate) The aorta above and below the aneurysm showed calcification. The vertebræ were not eroded. An electrocardiogram on May 6 showed left ventricular preponderance and a negative T wave in lead I (fig III) Radiography of the chest showed slight cardiac enlargement and some calcification in the arch of the aorta. Blood-count showed a moderate anæmia: red cells, 3,900,000; hæmoglobin, 84 per cent., colour-index, 1 08; white cells, 7200 (polymorphs 62 per cent, eosinophils 1 per cent., large mononuclears 9 per cent); no abnormal cells seen, size of red cells 7 81 μ Wassermann reaction negative. Fractional test-meal showed complete achlorhydria.

In July, 1938, the abdominal pain and vomiting and anginal pain became worse, the latter now coming on even while at rest in bed Blood-count: red cells, 2,600,000; white cells, 1800; Hb., 54 per cent; C.I , 1 05; size of red cells 7 64 μ; anisocytosis, poikilo-



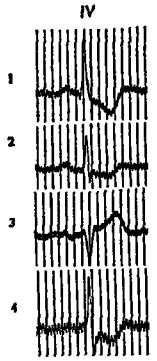


FIG III—Electrocardiogram, June 5, 1938 Left ventricular preponderance and negative T wave in lead 1

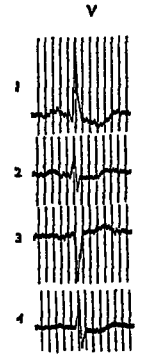
FIG IV—Electrocardiogram, July 26, 1938, during anginal attack Negative T waves in leads 1, 2 and 4, with depression of R–T interval and climbing T wave in lead 3



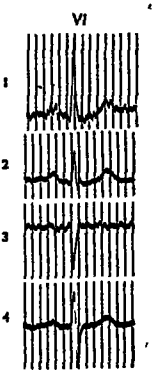


FIG V—Electrocardiogram, July 20, 1938 Negative T wave in leads 1 and 2 Left ventricular preponderance

FIG VI—Electrocardiogram, March 28, 1939 Normal. T waves in leads 1, 2 and 4 have become positive

cytosis, polychromasia and punctate basophilia, also a few normoblasts The soreness of the tongue was very severe The electrocardiogram taken on July 26, during an attack of anginal pain, showed negative T waves in leads 1, 2 and 4, with depression of the R–T interval and a "climbing" T wave in lead 3, the whole appearance being suggestive of a recent coronary occlusion (fig IV) Intensive liver therapy was then started, the administration of hydrochloric acid, which had been given previously, being continued After a few days of this treatment there was striking improvement in the patient's general condition and the anginal attacks ceased On the 29th the electrocardiogram showed a negative T wave in leads 1 and 2 and *left* ventricular preponderance (fig V) and resembled closely the electrocardiogram taken in *May*, 1938

Progress was rapid and continuous, and the patient was able to return home with a relatively *normal* blood-count, complaining of scarcely any abdominal symptoms beyond some abdominal discomfort and constipation All traces of anginal pain had gone On Jan 13, 1939, her blood count showed red cells, 4,400,000, Hb, 82 per cent; size of red cells 7 64 μ, some anisocytosis and poikilocytosis present The soreness in the tongue had entirely disappeared *On March 28* she felt quite well and her blood-count was red cells 4,600,000, Hb, 88 per cent, C I, 0 96 white cells 4600, size of red cells 7 3 μ, some anisocytosis and poikilocytosis The aneurysm was still felt pulsating in the abdomen The electrocardiogram on March 28 *showed no* abnormalities whatever, the negative T waves in leads 1, 2 and 4 having become positive (fig VI)

DISCUSSION

It has long been recognised that anginal pain is a common symptom in pernicious anæmia yet it is generally supposed that electrocardiographic changes are not found in cases of this type Thus Shirley Smith (1933), in a series of 15 patients *suffering* from severe anæmia of various types, took serial electrocardiograms without finding any electrocardiographic abnormalities or changes after specific anti-anæmic treatment He points out that in this respect pernicious anæmia and other severe anæmias differ from diabetes and other nutritional diseases in that he did find electrocardiographic changes in cases both of diabetic coma and hypoglycæmic coma Pickering and Wayne (1934) found no electrocardiographic changes even in those cases of pernicious anæmia in which angina was a well marked symptom It is true that Coombs (1926) suggests that certain electrocardiographic changes may be peculiar to severe anæmia, but he gives no particulars

There can be little doubt that, in the case described here, in addition to pernicious anæmia there were arteriosclerotic changes, this is shown by the presence of the aneurysm and the calcification in its walls When the patient was first seen, and when a relatively slight degree of anæmia was present, the electrocardiogram showed certain definite abnormalities such as left ventricular preponderance and a negative T wave in lead 1 Three months later, when an obvious and severe pernicious anæmia was present, symptoms of angina at rest had developed, and the electrocardiogram taken during an anginal attack was suggestive of a coronary occlusion Three days after the exhibition of liver therapy the angina had disappeared and the electrocardiogram, though still abnormal, was nearly the same as the first of the series After six months' liver therapy the electrocardiogram had become normal It is suggested that some arteriosclerotic coronary stenosis was present in this case, but that when the oxygen carrying power of the blood was normal this was not sufficient to cause ischæmia of the heart muscle When the oxygen carrying power was reduced by the pernicious anæmia beyond a certain point, however, myocardial anoxæmia developed, giving rise to the symptoms and electrocardiographic changes

I wish to thank the Director General of Medical Services Ministry of Pensions, for permission to publish this case, and Dr Arnold Stott for his kind help in preparing this report

HISTIOCYTIC MEDULLARY RETICULOSIS

BY RONALD BODLEY SCOTT, M.A., D.M. Oxfd, M.R.C.P.

FIRST ASSISTANT IN THE MEDICAL PROFESSORIAL UNIT, ST. BARTHOLOMEW'S HOSPITAL, LONDON; ASSISTANT PHYSICIAN TO THE WOOLWICH WAR MEMORIAL HOSPITAL, AND

A. H. T. ROBB-SMITH, M.A. Oxfd, M.D. Lond.

NUFFIELD READER IN PATHOLOGY IN THE UNIVERSITY OF OXFORD AND ASSISTANT DIRECTOR OF PATHOLOGY AT THE RADCLIFFE INFIRMARY

(*With Illustrations on Plate*)

In the century following Thomas Hodgkin's (1832) paper his syndrome resolved itself into a multiplicity of pathological entities. The leucoses, syphilitic and tuberculous lymphadenitis and lymphosarcoma (Kundrat 1893) were isolated; Sternberg (1898) and others established the histological features of lymphadenoma verum but there remained a number of cases which defied classification. These pathologists and clinicians alike have been accustomed to dismiss as "atypical Hodgkin's disease" It is of one group of these atypical cases that this paper treats.

Where the cause of a morbid process is unknown its diagnosis commonly rests on the changes in the patient's tissues, the ultimate analysis of which must be microscopical; thus in the group of diseases under consideration diagnosis can only be made with certainty by the microscope The histological criteria must be rigid, for if the cause be unknown it is irrational to assume that disease processes in two cases are identical unless the tissue changes are identical. The histological criteria for the diagnosis of Hodgkin's disease (lymphadenoma verum) have long been established (Sternberg 1898, Andrewes 1902, Reed 1902, Longcope 1903, Ziegler 1911) and there can be no justification for including under that head—even with the qualification "atypical"—cases which do not show the characteristic histological picture however close their clinical and anatomical resemblance to lymphadenoma verum. Progress will only be made when sufficient "atypical" cases have been collected to be submitted to histological analysis and classification

In an earlier paper (Scott and Robb-Smith 1936) we published three such cases and reviewed previous reports We concluded that a group of diseases exists which are characterised by a progressive cellular hyperplasia throughout the hæmopoietic and lymphatic tissues; these conditions differ from one another by virtue of the histological type or types of proliferated cells but owe their interrelation to the common mesenchymal origin of these cells. In some instances the proliferation has the characteristics of neoplasia, in others it does not transcend hyperplasia; but in all the change occurs in a systematised manner throughout the lymphoreticular tissue This group includes such apparently diverse diseases as Gaucher's syndrome, the leucoses and "atypical Hodgkin's disease" To these conditions have been applied the general descriptive title reticulosis (Letterer 1924, Pullinger 1932), or, if neoplasia be present, reticulosarcoma. Common examples of reticulosis are lymphoid leucosis (lymphatic leukæmia), where a systematised lymphocytic proliferation exists, and lymphadenoma verum in which there is a hyperplasia of reticulum cells (primitive undifferentiated mesenchymal cells) with differentiation to myeloid and fibril-forming elements. A suggested classification of the reticuloses and reticulosarcomata on a histological basis has recently been published by one of us (Robb-Smith 1938).

In this paper we are recording four examples of histiocytic medullary reticulosis and surveying the published reports of cases which appear to us similar. These cases will be seen to present a clear-cut clinical and pathological picture and give force to our contention that detailed analysis of the reticuloses will show the existence of unsuspected clinico-pathological entities. These cases illustrate what we have come to regard as the typical clinical course of the disease: fever, wasting and generalised lymphadenopathy are associated with splenic and hepatic enlargement and in the final stages jaundice, purpura and anæmia with profound leukopenia may occur. Post mortem examination shows a systematised hyperplasia of histiocytes actively engaged in phagocytosis of erythrocytes

First Case *

A married woman, aged 48, was admitted to St. Bartholomew's Hospital on July 19, 1929, complaining of weakness, cough and swellings in the neck and axillæ.

History.—Apart from "consumptive bowels" in infancy and appendicectomy for dyspepsia at the age of 36 she had had good health until four weeks previously when a swelling in the right occipital region had appeared; within the next few days this had been followed by swellings on both sides of the face and neck. She had felt ill and weak and had lost her appetite. Two weeks before admission similar swellings had appeared in both axillæ and groins and an unproductive cough had started. Exhibition of arsenic had been followed by diarrhœa. Her weakness and cough had grown worse and to them had been added shortness of breath.

Physical examination.—Temperature 104° F.; pulse frequency 110 per minute. She was dyspnœic and sweating; sordes were present and the tongue was furred. The fauces were dry and hyperæmic. *Small lymph-nodes were palpable in the occipital*, pre- and post-auricular groups and in all cervical triangles, both axillæ and groins. The epitrochlear nodes were not enlarged. In the chest there was increase in parasternal dullness with impaired percussion note and crepitation at the right base. The heart was normal. The liver was enlarged to 2 cm. below the costal margin and the spleen could not be felt.

Investigations.—Urine: a trace of protein, otherwise normal. Blood-count: erythrocytes, 4,580,000 per c.mm.; hæmoglobin, 86 per cent.; colour index, 0 93; leucocytes, 2200 per c.mm.—neutrophil 59 per cent. (1296), eosinophil 2 per cent. (44), basophil 0 5 per cent. (11), lymphocyte 35 per cent. (770), monocyte 3 5 per cent. (77).† Blood-culture: sterile. Wassermann reaction: negative. Skiagram of chest: enlargement of lymph-nodes in mediastinum and both hila; interlobar pleural thickening, right.

Progress.—Pyrexia continued with an evening temperature of 102°–104° F., her general condition deteriorated, a diffuse purpuric eruption appeared and the spleen became palpable. She died on Aug. 14 after an illness of eight weeks.

POST-MORTEM EXAMINATION AND HISTOLOGY

The body of a wasted woman with petechiæ on the face and trunk. Discrete enlargement of lymph-nodes in neck, axillæ and groins. Brain: natural. Heart: numerous petechiæ on pericardial surface and in muscle; no valvular defect. Upper air-passages: natural. Pleuræ: old adhesions at bases. Lungs: early basal bronchopneumonia; mediastinal

* This case was briefly described by Pullinger (1932)

† The figures in parentheses represent absolute numbers per c.mm.

and bronchial lymph-nodes enlarged, fleshy and hæmorrhagic Peritoneum and alimentary tract natural Mesenteric and retroperitoneal lymph-nodes enlarged Liver enlarged, pale and fatty Spleen 450 g soft, small white nodules scattered throughout its substance Kidneys subcapsular petechiæ Ureters and bladder natural Genitalia natural Thyroid, suprarenals and thymus natural

Lymph-node —The normal architecture is distorted by a proliferation in the medulla and lymph sinuses The lymph follicles can be distinguished but are compressed and consist entirely of small lymphocytes The cellular proliferation replacing the medulla consists of reticulum cells and large lymphocytes, but outnumbering these are cells of similar size to the large lymphocyte with irregular outline and almost filled by a round or oval nucleus rich in basichromatin, nucleoli are not present, the cytoplasm is eosinophilic and mitotic figures are plentiful These cells are regarded as "prohistiocytes" Numerous histiocytes with small dark nuclei and ingested particles are present Multinucleate cells are scanty and fall into two types the typical "mirror-image" giant-cell of Sternberg and Reed and a cell with an eosinophilic cytoplasm and a contorted nucleus rich in chromatin resembling the prohistiocyte The sinus lining cells show proliferation with prohistiocytes and mature histiocytes lying free in the lumina, phagocytosis of erythrocytes and debris is in process The whole node is congested and there are occasional areas of focal necrosis The reticulin framework although stretched is normal and there is no increase in collagen

Spleen —The organ is congested and shows many areas of focal necrosis Throughout the medulla these is a cellular proliferation similar to that described in the lymph-node Some malpighian bodies, consisting of small lymphocytes, can be seen but others appear to have been replaced by reticulum cells and prohistiocytes Active erythrophagocytosis is in progress and the sinuses are filled with proliferated littoral cells and prohistiocytes A few nodules consisting of reticulum cells and prohistiocytes are present in which mitoses are common The reticulin framework has not been altered but in the cellular nodules there are few fibrils Much iron-pigment is present

Liver —There is proliferation of reticulum cells and prohistiocytes in the periportal tissues The sinusoids are filled with prohistiocytes and proliferated Kupffer cells, many of the latter containing erythrocytes The parenchyma shows fatty infiltration and much iron-pigment is present in the hepatic and Kupffer cells

Bone-marrow —Erythropoiesis and granulopoiesis are accompanied by a proliferation of reticulum cells and prohistiocytes, but neither this change nor erythrophagocytosis are as prominent as in the other organs No adipose marrow was preserved for examination

Areas of similar cellular proliferation are present in the interstitial tissues of the kidney and myocardium and around the vessels and sweat-glands in the dermis

Second Case

Male, aged 31, meat porter Admitted to St Bartholomew's Hospital on Jan 5, 1932, complaining of weakness

History —He had always been healthy until seven months before admission when he had started to feel tired and short of breath on exertion With difficulty he had continued at work for another month when weakness had forced him to seek advice A month later he had been admitted to the Archway Hospital with relapsing pyrexia, splenomegaly and hepatic enlargement After a few weeks lymph-nodes had become palpable in the posterior cervical triangles Blood counts had shown a hypochromic anæmia with 65 per cent hæmoglobin and 3000 leucocytes per c mm without specific changes in the differential count but with polychromasia and basophilic stippling of the erythrocytes After three months in hospital a zoster of the eighth right thoracic segment had appeared, accompanied by severe pain Two months later he had returned home, but after three weeks he had attended St Bartholomew's Hospital on account of a swelling in his neck and had been admitted on the same day

Physical examination —Temperature 102° F, pulse frequency 120 per minute He was pale and emaciated There were patches of alopecia at the nape of the neck and shotty lymph-nodes could be felt in all cervical, axillary and inguinal groups, the epitrochlear nodes were not palpable At the angle of the jaw on the right side was a soft swelling, unattached to the skin, measuring 4 by 2 cm The lungs were normal and a systolic murmur was audible at the cardiac apex A healing zoster was present over the right 6th, 7th and 8th thoracic segments where the skin was glossy, red and indurated The spleen was enlarged to 22 cm below the costal margin and the liver to 13 cm, both were firm and insensitive Signs of a small ascites were present

Investigations —Urine normal Blood-count: erythrocytes, 2,850,000, hæmoglobin, 53 per cent; colour-index, 0·9, leucocytes, 844—neutrophil young form 1 per cent (8), segmented 62 per cent (523), lymphocytes 27 per cent (227), monocytes 9 per cent (70), unclassified 1 per cent (8) Van den Bergh's reaction direct, negative, indirect, 0·25 mg bilirubin per 100 ml serum Wassermann reaction negative Skiagram of chest normal

Progress —Pyrexia, with an evening temperature reaching 103° F, continued and on Jan 22 he complained of sore-throat, his leucocyte count at this time was 968 per c mm He became progressively worse with cough, stridor and dysphagia, finally developing jaundice and dying on Jan 31, after an illness lasting nearly eight months

POST-MORTEM EXAMINATION AND HISTOLOGY

The body of a wasted jaundiced man with a diffuse petechial rash Discrete enlargement of lymph-nodes in neck, axillæ and groins Brain natural Heart subpericardial hæmorrhages Larynx: recent perichondritis with gangrene of overlying mucosa, sinus below and behind left vocal cord Pleura natural Lungs congestion and basal bronchopneumonia, mediastinal lymph-nodes enlarged, fleshy and hæmorrhagic Peritoneum and alimentary tract natural, mesenteric and retro-peritoneal nodes enlarged Liver 2000 g, surface pale with petechial hæmorrhages, on section uniformly pale and friable Spleen 950 g, adherent to surrounding viscera, two old and two recent infarcts, on section, dark red with scattered white nodules Kidneys, ureters and bladder natural Genitalia, thyroid and suprarenals natural Femoral bone marrow dark red throughout length of shaft with scattered small white firm areas

Lymph-node —A cellular proliferation is present in the medulla which has the same characteristics as in case 1 but lymph follicles can no longer be recognised and there is compression of the sinuses Reticulin fibrils are increased but there is no excess of collagen, erythrophagocytosis is prominent

Spleen —Apart from the infarcts the changes are similar to those in the lymph-node It is still possible to distinguish occasional malpighian bodies and these are often surrounded by an increase of reticulin fibrils The littoral cells show some hyperplasia but the chief change is in the medulla Erythrophagocytosis is pronounced but iron pigment scanty

Liver —The hepatic parenchyma shows extreme fatty infiltration Cellular proliferation with an increase in reticulin fibrils is found in the periportal tissues The Kupffer cells are hyperplastic and engaged in erythrophagocytosis

Bone-marrow —Cellular proliferation with ingestion of erythrocytes is occurring side by side with a patchy hæmoblastic reaction

Third Case

Male, aged 41, caretaker. Admitted to St Bartholomew's Hospital on Oct. 23, 1936, complaining of weakness

History.—He had had a mastoid operation at the age of 18 and a shrapnel wound in the left ankle during the war; otherwise his health had been good until four weeks before admission when after a day of heavy mowing he had suddenly felt weak and short of breath. He had remained at work for a further week with a sense of increasing exhaustion. At that time he had taken to his bed because of sudden swelling of his legs; this had lasted only three days but had been followed by persistent fever with sweating at night

Physical examination.—Temperature 101·2° F.; pulse frequency 90 per minute. He was thin, pale and sweating Dental infection was present with gums which bled when touched Small mobile discrete lymph-nodes were palpable in both posterior cervical triangles, both axillæ and groins, the epitrochlear nodes were not enlarged Scattered bronchitic sounds could be heard throughout both lungs. The heart was normal. The spleen was enlarged to 8 cm. below the costal margin and the liver to 3 cm.

Investigations.—Urine: normal Blood-count: erythrocytes, 2,780,000; hæmoglobin, 50 per cent; colour-index, 0·89, polychromasia and anisopoikilocytosis present; leucocytes, 1000—neutrophil young forms 1 per cent (10), band forms 7 per cent. (70), segmented 48 per cent. (480), lymphocytes 31 per cent. (310), monocytes 13 per cent. (130), platelets 70,000 per c.mm Sternal puncture: moderately cellular films; a promyelocytic type of granulopoiesis and active orthoplastic erythropoiesis. Adrenaline response: no primitive cells in blood. Van den Bergh's reaction: direct, negative; indirect, 0·2 mg. bilirubin per 100 ml. serum. Wassermann reaction: negative Skiagram of chest: normal.

Progress.—His condition gradually deteriorated; pyrexia continued reaching 105° F. on some evenings. On Nov 18 jaundice appeared which was followed by a generalised purpuric eruption, his leucocytes sank to 750 per c.mm with 56 per cent. neutrophils and his platelets to 8200 per c.mm. He complained of pain in the throat and examination showed a necrotic angina. On Nov. 26 he died after an illness of eleven weeks.

POST-MORTEM EXAMINATION AND HISTOLOGY

The body of a wasted jaundiced man with petechiæ on the trunk and abdomen. Discrete enlargement of lymph-nodes in neck, axillæ and groins. Brain: natural. Heart: natural. Pharynx: necrotic ulceration with sloughing of epiglottis Pleuræ: natural. Lungs: œdematous and congested; confluent bronchopneumonia right lower lobe; mediastinal and bronchial nodes enlarged, fleshy and hæmorrhagic. Peritoneum and alimentary tract: natural; mesenteric and retroperitoneal nodes enlarged. Liver: 2200 g.; cut surface green-yellow. Spleen: 1720 g.; several infarcts; cut surface soft and dark red. Kidneys, ureters and bladder: natural. Genitalia, thyroid and suprarenals: natural. Femoral bone-marrow: red throughout shaft.

HISTOLOGY

Lymph-node.—The histology is similar to that seen in cases 1 and 2 but in many of the nodes the medullary cellular pattern is loosened by a fibrinous exudate and it is in these zones that hæmorrhage has occurred Phagocytosis is active but there is little free iron The sinuses are compressed but littoral-cell activity can be seen. There is no increase in reticulin or collagen. In the periadenoid connective tissue of some of the nodes there is a proliferation of cells similar to those in the medulla

Spleen.—The degree of medullary hæmorrhage and necrosis is more marked than in any of the other cases but the histology is similar; medullary phagocytosis is active and the sinusoids are compressed. There is a moderate amount of free iron.

Liver.—The hepatic parenchyma is well-preserved though there is biliary retention in the central zones. In the periportal areas the cellular proliferation is considerable, consisting chiefly of reticulum cells, prohistiocytes and cells of the lymphoid series with few active phagocytes The Kupffer cells are proliferated and actively phagocytic. There is a moderate amount of free iron in the Kupffer cells and in the hepatic cells at the periphery of the lobules.

The *bone-marrow* is extremely congested and hæmorrhagic but it is not highly cellular; foci of cells of the histiocytic series are present.

Lung.—A subpleural nodule 0·5×0·6×0·8 cm. consists of a localised area of reticular cellular proliferation. The alveolar walls are thickened by collections of reticulum cells and lymphocytes; the alveoli are filled with alveolar phagocytes. There is no fibrosis nor bronchiolar obstruction to suggest that this is a secondary change.

Fourth Case

Farm-labourer, aged 52 Admitted to the Radcliffe Infirmary, Oxford, on Jan 3, 1939, complaining of weakness and abdominal pain

History.—For many years he had been deaf and this affliction coupled with a sluggish intellect made it impossible to obtain an adequate history For some years past he had suffered from abdominal pain but during the past three months this had become worse and he had begun to feel weak. These symptoms had increased until he had been forced to consult his doctor four days before his admission.

Physical examination.—Temperature 101° F.; pulse frequency 120 per minute. He was wasted and pale with a malar flush. The mouth and pharynx were normal. Firm discrete mobile lymph-nodes were palpable in the right axilla and both supraclavicular groups. The heart and lungs were normal. The liver was enlarged but the spleen could not be felt.

Investigations.—Urine: normal. Blood-count: erythrocytes, 1,490,000; hæmoglobin, 29 per cent.; colour-index, 1·0; considerable anisopoikilocytosis; leucocytes, 1900—neutrophil band form 6 per cent. (114), segmented 48 per cent. (912), eosinophil 1 per cent (19), lymphocyte 37 per cent (703), monocyte 8 per cent. (152). Wassermann and Meinicke reactions negative.

Progress.—His condition deteriorated with a regular intermittent pyrexia reaching 100°–102° F. in the evening and a tachycardia of 120–140 per minute His spleen became palpable and on Jan 13 an extensive purpuric rash appeared with œdema of the feet He died on the 18th after an illness which had probably lasted about three months.

POST-MORTEM EXAMINATION AND HISTOLOGY

The body of a wasted man with a purpuric eruption on the back; there was no jaundice. Moderate enlargement of lymph-nodes in neck, axillæ and groins Brain: natural. Heart: organising hæmorrhagic pericarditis; dilatation of all the cavities; fatty degeneration of the myocardium. Upper air-passages: natural; slight enlargement of the pharyngeal lymph-nodes which were dark red in colour Pleuræ: no effusion; old adhesions at the left apex and right base Lungs: pale and œdematous; old area of cavitation at the left apex. Mediastinal and tracheobronchial lymph-nodes: slightly enlarged. Peritoneum and alimentary tract: petechiæ on the œsophageal mucosa; the rest of the tract was natural and the lymphoid tissue was not increased in amount; the paraortic and mesenteric nodes were slightly enlarged, firm, discrete and hæmorrhagic Liver: 2130 g., pale with areas of periportal pallor suggestive of an infiltration Spleen: 954 g.; no perisplenitis; cut surface soft with an extremely congested pulp in which there were dark areas suggesting blood lakes; the trabeculæ and follicles could not be identified. Kidneys, ureters and

bladder natural Genitalia and endocrine glands natural Bone-marrow dark red marrow extending over three-quarters of the length of the femoral shaft The sternal and vertebral marrow was of a similar colour

Lymph-nodes.—These were examined from a number of areas and all show changes similar to those described in the other cases, though the hæmorrhagic character is not so marked and the essential medullary origin of the proliferation is obvious, the œdema and fibrinous exudate observed in case 3 are also present In places the follicles can still be recognised, the littoral cells in the sinuses are hyperplastic and contain some iron pigment There is no fibrosis nor periadenoid cellular proliferation

Spleen.—The medullary proliferation of prohistiocytes and actively phagocytic histiocytes is considerable as are the hæmorrhagic œdema and fibrinous exudate, necrosis is not marked The venous sinuses are compressed but the medullary blood lakes are liable to be mistaken for dilated venous sinuses unless reticulin impregnations are examined There is much free iron in the medullary histiocytes

Liver.—There is periportal and Kupffer-cell proliferation and much free iron-pigment in the liver cells and histiocytes

Bone marrow.—There is an active orthoplastic erythropoiesis with foci of the abnormal reticulum cells and at the periphery of these zones the histiocytes show ingestion of erythrocytes

There is also a proliferation of prohistiocytes in the interstitial tissues of the heart-muscle and kidney and in the alveolar walls of the lungs

Previously Reported Cases

We have found records of the following similar cases:—

TSCHISTOWITSCH AND BYKOWA (1928).—Male, aged 63, with two months' illness characterised by weakness, fever and cough Pyrexia, jaundice, left-sided pleural effusion, œdema of legs, generalised lymph-node enlargement Urine urobilin, no bile pigment Blood-count erythrocytes, 3,720,000, hæmoglobin, 69 per cent, leucocytes, 6600 (differential count normal)

Left-sided pleural effusion Spleen 500 g, dark red and firm Liver, 1650 g, pale with occasional nodules Generalised lymph-node enlargement Spleen and nodes occupied by diffuse proliferation of reticulum cells and histiocytes, many of the latter showing erythrophagocytosis, moderate phagocytic activity of littoral cells, some increase of reticulin in medulla Liver periportal proliferation of reticulum cells and actively phagocytic histiocytes Bone marrow foci of similar change

BYKOWA (1929).—Female, aged 69, died after an illness of six weeks with generalised lymphadenopathy, splenomegaly, jaundice and *consolidation* of upper lobe of right lung Blood count erythrocytes, 2,010,000, hæmoglobin, 49 per cent, leucocytes, 1800 (10·5 per cent neutrophils), platelets 27,170 Leucocytes later fell to 1000 per c.mm

Spleen 18 × 13 × 10 cm Normal architecture replaced by proliferated histiocytes and atypical phagocytic cells, no reticulin increase, some littoral phagocytosis Liver periportal cellular proliferation, phagocytic activity of Kupffer cells Bone marrow little hæmopoietic tissue but great increase of actively phagocytic reticulum cells Lungs increase of alveolar phagocytes

DERISCHANOFF (1931).—Female, aged 26, with an acute illness associated with weakness, pallor and splenomegaly Blood count erythrocytes, 650,000, hæmoglobin, 30 per cent, leucocytes, 7000 (differential count normal) Splenectomy followed by death

Spleen, 2100 g, great phagocytic activity in medulla and sinuses with a little reticulin increase Lymph-nodes similar Liver localised nodules of phagocytic cells and increased activity of Kupffer cells

DAMESHEK (1933).—Male, aged 39, with weakness and intermittent pyrexia for six months On examination three months before death generalised lymphadenopathy with splenic and hepatic enlargement Blood-count erythrocytes, 2,830,000, hæmoglobin, 55 per cent, leucocytes, 3500, later falling to 1100 with 69 per cent neutrophils

Spleen, 310 g, several infarcts and grey-yellow nodules, medulla replaced by proliferation of large polymorphic cells with dark nuclei, marked siderosis and erythrophagocytosis Lymph-nodes similar Liver brown red with grey nodules, periportal cellular proliferation, Kupffer cells active Bone-marrow similar changes

NORDENSON (1934).—Female, aged 65, with five months' illness attended by pain in sacrum, weakness and emaciation Blood-count erythrocytes, 1,800,000, hæmoglobin, 37 per cent, leucocytes, 4800

Spleen, 350 g, follicles small; pulp and sinuses replaced by large *cells containing much hæmosiderin* Lymph-nodes similar changes Liver enlarged, red-brown, sinusoids filled with atypical darkly staining cells containing hæmosiderin, no clear distinction between periportal cells and those in sinusoids. Bone marrow similar

BEAVER AND JOHNSON (1934).—Female, aged 26, with three months' lassitude, irregular fever, diarrhœa and abdominal distension Blood-count erythrocytes, 1,500,000, hæmoglobin, 68 per cent, leucocytes, 7100

Bilateral pleural effusions, inactive rheumatic valvulitis, *ascites* Spleen, 300 g, purple hæmorrhagic nodules on cut surface; follicles small, sinuses engorged, cellular proliferation throughout medulla with active phagocytosis and areas of necrosis Lymph nodes generalised enlargement with histological changes similar to those in spleen Liver, 2250 g; nodules on capsule and numerous hæmorrhagic *areas on section*, *necrosis of parenchyma* periportal proliferation of atypical histiocytes and giant cells, Kupffer cells inactive

Discussion

The clinical picture.—The uniformity of these ten cases justifies an attempt to describe a clinical picture All the patients were adults and the sexes were equally represented

The disease was ushered in by asthenia, emaciation and a profound general intoxication accompanied by high, and sometimes relapsing, pyrexia The lymph nodes were enlarged in nine of the ten cases and although this change was usually generalised and moderate in degree, in some instances enlargement of one group predominated Splenomegaly was present in all and in eight the liver was palpably enlarged Seven cases showed jaundice in the later stages and where details are available they suggest haemolysis as its basis In our four cases a terminal purpuric eruption was noted

The blood changes serve to distinguish the disease from acute leucosis although sternal puncture may be required to exclude the leucopenic variety Anæmia was constantly present but its severity was usually in direct ratio to the duration of the illness, it was commonly normocytic but in some macrocytosis was a feature Leucopenia was present in seven cases and in two of those reported here was profound enough to be associated with necrotic angina, the differential count however did not show agranulocytosis but a proportional reduction in all leucocytes with some "shift to the left" of the neutrophils There was thrombocytopenia in the two cases in which platelet counts were made

The course was rapid and all cases terminated fatally, the shortest after six and the longest after thirty two weeks, the mean duration was fifteen weeks.

Pathology.—At post mortem examination the general changes common to cases of profound anæmia

coexisted with wasting, jaundice and cutaneous and subserous petechiæ. The characteristic findings were confined to the lymphoreticular tissues There was generalised moderate enlargement of lymph-nodes which individually were discrete and soft, showing on section a pink surface with areas of hæmorrhage Splenic enlargement was of varying degree (310–2400 g, mean 880 g); infarction with overlying perisplenitis was common and the cut surface was maroon in colour with raised paler areas 0·5–2·0 cm in diameter: the malpighian bodies could not be seen and although the pulp was soft it was not diffluent. Enlargement of the liver was the rule; on section the organ was pale with areas of hæmorrhage, while lighter zones could be distinguished in the periportal tissues The marrow of the long bones was commonly red, hæmorrhagic and interspersed with firmer pale nodules In some cases the lymph follicles of the intestine were prominent and in others subcutaneous nodules were found.

The histological changes consist in a systematised cellular proliferation throughout the lymphoreticular tissues together with siderosis which is most intense in the hepatic parenchyma and the Kupffer cells. These changes occur in the lymph-nodes, the medulla of the spleen, the periportal tissues and focally in the bone-marrow and dermis. They are similar in all these situations and a detailed description will be limited to the lesion as seen in the lymph-node, for here all the characteristic appearances are gathered together in a small compass

The normal structure of the node is modified by a cellular proliferation in the medulla; in some cases the follicles, although compressed, can yet be distinguished, in others they are obliterated by a proliferation around their central arterioles The littoral cells of the lymph sinuses are often hyperplastic and actively engaged in erythrophagocytosis The proliferation in the medulla is composed of reticulum cells and large lymphocytes but overshadowing these are numbers of cells of the histiocytic series Some are typical histiocytes containing erythrocytes and nuclear debris; others, which we regard as their precursors, are non-phagocytic These prohistiocytes (Scott and Robb-Smith 1936) have a diameter of 12–14 μ with irregular contour and a pachychromatic nucleus averaging 9 μ in diameter which is set in an opaque eosinophilic cytoplasm. Mitotic figures are often found and giant prohistiocytes are not uncommon, their twisted nuclei, rich in basichromatin, contrasting sharply with the pale "mirror-image" nucleus of the Sternberg-Reed giant reticulum-cell of which examples are also frequently seen. Areas of hæmorrhage, fibrinous exudate and coagulative necrosis occur in the medulla, and although silver impregnation at times shows an increase in reticulin there is no excess of collagen and no fibrosis

It should also be emphasised that the cellular proliferation and active phagocytosis is predominantly in the medullary portion of the nodes In many bacterial infections—for example subacute bacterial endocarditis—there is often a considerable proliferation of the littoral cells in the liver, and elsewhere, with much phagocytosis; but in those conditions there is no proliferation in the medullary portion of the spleen or lymph-nodes nor in the periportal areas of the liver; further, the large number of the prohistiocytes and the hæmorrhagic areas secondary to the œdema and fibrinous exudate are characteristic changes in histiocytic medullary reticulosis.

It remains but to stress the differences between the histological appearances just described and those of lymphadenoma verum where the cellular proliferation in the medulla is pleomorphic with myeloid elements and fibrosis but without notable erythrophagocytosis.

The clinical and morbid histological picture exhibited by our four cases and by the other six recorded is sufficiently uniform to justify our contention that they are examples of a disease process sui generis. Neither the course of the disease nor the morbid histology of the lesions resemble those of Hodgkin's disease. These cases show a closer affinity with acute leucosis, but in them the systematised hyperplasia affects the histiocytes and their precursors and not the leucopoietic cells For this condition we have suggested the histologically descriptive name "histiocytic medullary reticulosis"

Conclusions

1 Four cases are recorded of a clinical and pathological entity for which the name "histiocytic medullary reticulosis" is suggested.

2 This condition has previously been accepted as a form of "atypical Hodgkin's disease," although the two disorders are in fact dissimilar and unrelated.

3 Previous reports of six similar cases have been found.

4 The clinical course is characterised by fever, wasting, generalised lymphadenopathy, splenomegaly and hepatic enlargement. In the terminal stages jaundice, purpura, anæmia and profound leucopenia are common. All cases ended fatally.

5 The pathological findings are a systematised proliferation of erythrophagocytic histiocytes and their precursors throughout the lymphoreticular tissue.

Our thanks are due to the physicians to St Bartholomew's Hospital and to Dr A G Gibson for their permission to publish these cases.

This work was done during the tenure of a grant from the British Empire Cancer Campaign.

". The highly educated minority seems to be close to the crossroads in the progress of higher learning Their leadership in thought and practice can continue only as they find effective ways to distribute useful knowledge and service and to lead the majority toward sympathetic participation in advancing knowledge The mass of knowledge-consumers and users, even though they are not primarily discoverers, now need, and sometimes expect or demand, enough insight into new knowledge that they may appreciate its significance"—Dr OTIS W. CALDWELL, general secretary of the American Association for the Advancement of Science, *Science*, June 30, 1939, p. 595

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTION OF PSYCHIATRY

At a meeting of this section held on July 11, with Dr H. CRICHTON-MILLER, the president, in the chair, a discussion on

Euthanasia and the Psychoses

was opened by Mr H H GREENWOOD He outlined the history of the movement in favour of voluntary euthanasia, and the provisions of the bill to which the House of Lords refused a second reading in December, 1936, largely on the advice of Lord Dawson and Lord Horder The bill provided that a person suffering from an incurable and fatal illness which involves severe pain may apply to receive euthanasia He must be of sound mind and have attained majority The application must be accompanied by two medical certificates, one from the sufferer's own medical attendant and one from an independent practitioner these were to be sent to a referee, an official of the state, who if he saw fit could issue an official permit The person to administer the euthanasia would be a medical practitioner licensed for that office Mr Greenwood summarised the objection to the bill on the ground of the sanctity of human life It is admittedly difficult, he said, especially in psychiatry, to declare that a given condition is incurable before the introduction of malarial treatment and convulsion therapy general paralysis of the insane and schizophrenia were believed to be incurable Clearly the 'independent practitioner" must be an alienist, as he must assess the patient's soundness of mind The law, always suspicious of the integrity or the capacity of the alienist, is apt to make the facile generalisation that an act of self-destruction is of itself evidence of unsoundness of mind. Mr Greenwood suggested that if an applicant for euthanasia made a will, his application might raise doubt of his testamentary capacity No medical man would accept the office of administrator of euthanasia, but if the final administration is made by the patient it is an act of suicide, and the problem is removed to a different plane

The bill laid emphasis mainly on bodily illness and suffering Twenty per cent of suicides, however, occur in the insane Mental pain may be sufficiently dreadful as a concomitant of physical illness, but the mental pain of the psychopathic and the insane is a terra incognita explored only by the psychiatrist and probably outstrips in intensity any physical suffering No sane person can comprehend the suffering that impels the melancholic to suicide The sane sufferer begs for euthanasia, but the suicidal insane person demands death imperatively Driven by an inner compulsion, he will make the opportunity to achieve it Mr Greenwood asked whether the term "voluntary euthanasia" excludes those who are demonstrably insane and who not only seek death but demand it

Dr LETITIA FAIRFIELD said that at first sight the suggestion that euthanasia should be available to psychotics is singularly attractive No human misery is so excruciating to the sufferer and so painful to the onlooker, and in no state does the patient more frequently give the strongest demonstration that he wishes to be rid of his life Death as envisaged by the psychotic may be coloured by the nature of his illness, and probably also depends on the conception of death which is in the minds of most persons The large proportion of suicides are probably psychotic There is hardly any form of psychosis in which the desire to end life may not find expression at some time or another Some deaths may be interpreted as panic stricken pell mell flight from intolerable anguish, mental or physical, in others the motive is more subtle A belief in immortality is found among all races and religions The desire for death has been interpreted by psychologists as a longing to return to the mother's womb, and the beatific vision, or the Buddhist ideal of Nirvana, has been held not very different from the concept of the return to the prenatal existence This picture is, however, said Dr Fairfield, wholly incomplete unless its ambivalent character is recognised The dread of death is as profound as the longing for it The psychotic, like the sane person, has this instinctive dread of the unknown, of this second trauma which completes and cancels out the first trauma of birth His dread may be temporarily conquered by his disappointment or pain, but it remains an essential part of his mental equipment

The feeling of guilt and judgment is the very basis of some psychoses It has little or nothing to do with theories of the after life, religious belief or previous conduct To many persons, especially later in life, it makes death a very dreadful thing; this dread may even impel a patient to kill himself—to fling himself into the abyss into which he dreads to fall The teachings of the Christian religion are relevant to this inquiry because they form an important part of the training and the fundamental beliefs of most mental patients Just as a Christian may not flee from death at the cost of honour, so he may not seek it without the permission of the Creator. Would the psychotic, asked Dr Fairfield, be grateful for death if it were offered him? Would a death agreed to and inflicted by others meet his peculiar demand? The fear of death might rather add infinitely to the terror at present attached to mental disease in the mind of the public She asked whether the bill proposed that the psychotic is to be dealt with only on his demand Would the method of suicide be left to his choice? Is it proposed that mental hospitals should have licensed suicides whose point of view has been approved by some tribunal and who are at liberty to destroy themselves in any way they prefer, and a second class of patients whose application is before the Ministry of Health, and a third class whose application has been rejected and whose misery may thereby be increased?

When a reformer first begins to argue that these rights of life and death are in the hands of the individual to be exercised on hedonistic motives, recognising no higher rule, he finds himself in the same position as those who advocate that a woman should be allowed the right of abortion by her free individual choice, subject to the control of a tribunal The proposal to set up a tribunal and official machinery completely negatives the supposed right of the individual and the proposition is reduced to an absurdity, for the two halves of it are incompatible

The most acutely agonising mental conditions are curable disorders Are the authorities (asked Dr Fairfield) going to deny a patient's right to commit suicide because they hope his condition is curable, and if so, how long must he wait? Are they to consider the degree of the patient's agony, or the validity of their own prognosis? The manic-depressive

between his attacks thinks life worth living, and that interval, when he has a balanced judgment, is the time when he should make his decision It would be quite impossible to make the public understand the precise limit of the psychiatrist's power under any bill which proposed euthanasia for the insane Public opinion has passed with difficulty through an era of the most profound distrust of the mental hospital. One of the popular beliefs concerning mental hospitals and public institutions has been that "they do you in" Gradually that belief has been conquered —but the advocates of euthanasia apparently propose to make it true If they had their way, then a consequence of psychosis would be that, perhaps for the patient's own good, at any rate on someone else's opinion, the power over his life would pass into the hands of another. That is the fundamental proposition the limits of which cannot be exactly defined and the terror of which would cast an extra shadow over the gathering clouds which even now make an approaching psychosis terrible enough Psychiatrists would be better concerned in looking after the welfare of their patients in this world than in hurrying them into a world of the terms of entrance into which they know very little, except that gate-crashing is prohibited.

Dr IAN SKOTTOWE suggested that the possibility of euthanasia might lead to a diminution of effort in the attempt to find a cure In dealing with the psychotic the whole question turns on the word "suffering" Are psychiatrists, he asked, so sure that the melancholic is in fact suffering an agony comparable to that of the cancer patient? Work done at Cardiff on psychogalvanometric and blood-sugar responses indicates that the patients who harp most continuously on death and ask most vehemently to be allowed to die are those whose responses show the least real emotion and feeling He agreed that the patients who may be believed on objective grounds to experience true suffering are the ones who are likely to recover If the Freudian view of melancholia is correct—the inturning of the sadistic impulse and a regression to earlier levels—then the patient is enjoying his suffering and there is no argument for putting him out of it We have only to look round to see the position which we have reached through our appalling habit of solving every personal problem by making a rule about it Rules are generally made as a substitute for personal responsibility, and they will never be an effective one In the problem of euthanasia the personal responsibility is twofold: that of the patient and that of the doctor, of the two the doctor is probably the less well-adjusted and therefore the less well-fitted to decide on the patient's fate It is not credible that the Divine permission can be granted at the pearly gates of the Ministry of Health, or be personified by the Home Secretary This is not a problem for legislation If the psychiatrist can first clarify his personal problem and then by empathy feel himself into the patient's situation and ask himself whether he in that situation would hang on or give up as long as a spark remained, the answer would almost certainly be that he would hang on

Dr C O. HAWTHORNE criticised the bill for proposing to introduce a fresh cause of distress to friends and relatives It treated the patient as though he were completely isolated Every practitioner knows that such a proposal would if enacted lead to the most anxious discussion in family circles whether a father or mother should or should not be encouraged to an act of suicide After the death, relatives would always be found to say that it should not have been allowed and to quote similar cases in which the patient had recovered. He objected to the proposal to lay this duty on the doctor If euthanasia became the law of the land, the state must find an executive officer.

Dr MURDO MACKENZIE pointed out that extreme pain leads commonly to distortion of mental rhythm, which must invalidate the patient's soundness of mind.

The PRESIDENT emphasised the difference between the expiatory motive in suicide and the desire to die To be put to death by the act of another would not satisfy the unconscious motive of the expiatory suicide. his death has to be at his own hands The demand for death in a mentally disordered person is probably akin to the common demand of patients for change of environment, to be allowed to go away. The request is purely destructive and is a result of a projection of the mental state on to the environment. The act of putting a person to death is often disastrous to the mental integration of a judicial executioner, and in a case which the President quoted a man who had given his father, speechless with pain, an overdose of morphia in the conviction that he was acting rightly, had none the less suffered a severe neurosis It is not in human nature, he concluded, to be an executioner on a rational basis, and we ought perhaps to be thankful that it is not.

ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION

THE annual meeting of this association was held in the Royal Pavilion, Brighton, on July 12

Presidential Address

Dr HELEN BOYLE, in her address "Watchman, what of the night?" said that she hoped to show that, in mental medicine, night was departing and day approaching. The first great step in this country was taken by the late Dr Rayner. He realised clearly that patients in a mental hospital had often suffered for a long time before being admitted, and that by early treatment they might have recovered before reaching the stage at which they could be certified He found that these patients presented themselves first at the general hospitals, sent often by their local doctors He therefore persuaded St Thomas's Hospital to establish an outpatient department for them in 1889, and worked in it himself till 1905 Dr Percy Smith had exceptional opportunities for observing the earliest certifiable patients at Bethlem and later he started the second outpatient clinic at Charing Cross Hospital Dr Goodall's clinic at the Cardiff Hospital took the movement to the provinces Many were the quips and jeers in those days, and yet the public on the whole has been more readily convinced of the value of early treatment in mental medicine than the medical profession itself. Now the idea is slowly seeping into the minds both of the profession and of the people at large that every general hospital is failing in its duty if it does not have at least an outpatient department for nervous patients Sir Maurice Craig was the pioneer of physical and mental rest (now sometimes expanded into prolonged narcosis) He put numbers of his patients to bed for rest-cures, with or without massage This in the early days caused laughter

I recall that one of the rare differences of opinion I had with my very good head attendant at Claybury was when I insisted on keeping some of my feebler patients in bed She warned me that if the commissioners came they would be much annoyed to see so many in bed Sir Maurice Craig also did more probably than anyone else in this country to help the rank and file of the profession to appreciate the physical side of mental and nervous breakdowns At this time there came a new trend of thought—the study of the emotions and their influence on character and conduct From the welter of differing psychotherapeutic theories which developed it is possible to distinguish the gradual emergence of a type which, being a compromise, is dear to British hearts This sound and sensible practice avoiding extremes may ultimately be called the British school

The next great practical step was taken by the late Dr Carswell of Glasgow, who started under the local authority in 1904 two wards separate from the infirmary, but close to it, into which he admitted those nervous and borderland patients whom he regarded as in need of treatment but who were not certifiable Then in 1905 the "Lady Chichester Hospital" was started We were convinced that its right place was in close association with a general hospital, and our little hospital was offered at the time of its birth to the Royal Sussex County Hospital The offer was refused, although I was willing to make myself responsible for the financial side for a number of years The start was therefore made independently by our clinic on £200 and a lot of faith By slow degrees the hospital grew and was found useful, particularly in the Great War when we took in patients with breakdowns from war service and air raids The Lady Chichester Hospital later found its present home in New Church Road, Hove, and in 1930 the Royal Sussex County Hospital, on the proposal of Dr Broadbent, itself suggested a liaison with us It started an outpatient clinic for early nervous cases and we gave six beds for men and six for women

What of the future? There are, and should be, in any living movement, differences of opinion as to methods, there should be none as to the aim For us the aim is to find for this nation, and, as far as in us lies, for all nations, the best means of prevention and the best treatment for nervous and mental instability, and thus to establish a wise and secure mental adjustment Numbers of us are already battling with the intricate obscurities of the psychological questions in unemployment and malnutrition and the origin of the psychoses and psychoneuroses, but consider the most urgent problem of all It is easy to say "No one in their senses would ever make another war, it would probably exterminate our civilisation" Everyone agrees But nothing except a universal mental readjustment can stop wars

A movement gaining momentum every year is the movement for a better training, both of the medical student and of the young postgraduate, in psychological medicine We must throw open the doors of our mental hospitals not only to the voluntary patients but to any medical men and women who wish to gain experience in this most difficult specialty Geographical difficulties are still considerable It is to be hoped that local authorities, in choosing sites in the future, will realise the value of close relations between hospitals of all kinds, the medical profession, the social services and the patients' friends

In conclusion, may we in this country never lose individual vision, freedom to realise it, and the generously given voluntary work which is almost a distinctive feature of Great Britain—being jeopardised at present but it is worth fighting for Once lost it will hardly be regained.

Securing Early Treatment

Dr W J T KIMBER (St Albans) said that for inquiring into the mental, bodily and environmental state of the patient a medical and psychiatric team of workers was required, and such teams were available only at the larger general hospitals Their cost must if necessary be met by the local authority The director should be a psychiatrist with broad general medical and surgical experience, the personnel should include a psychiatrist, part time paid psychotherapists, a social worker and (for child guidance clinics) a psychologist Psychotherapists should have had a personal training analysis The child guidance unit could be at a general hospital, or at the mental hospital, or elsewhere, but all the mental health services should be incorporated in a definite scheme Beds were a necessity for any clinic beds in a small clinic or a hospital ward were useful provided they were suitably staffed, beds in a mental hospital with a progressively educative and recreative regime were of greater value, but would not be acceptable to the public unless the amenities, and the classification of patients were considerably better than they were at present in most mental hospitals

Dr JAMES TILAD (London) said that "long" and "short" psychotherapy differed not merely as regards the number of interviews or the length of treatment, but also in the method of approach to the patient by the doctor, the social worker and others concerned in his treatment Only patients of high intelligence and sufficient education were suitable for prolonged and deep analytic treatment In 100 cases of psychoneurosis referred to the out patient department of the Lady Chichester Hospital only 4 were thus treated The incidence of physical illness in the series had been high, and the department gained greatly by having a hospital back ground He was satisfied that help could be given even to the chronic psychoneurotic, one must assess the patient's optimum and make this the objective Inpatient care was required (1) when treatment must be prolonged and intensive, (2) when physical conditions demanded complete rest, (3) when the patient must be removed from his environment, or (4) when the diagnosis between psychoneurosis and neurosis was in doubt Most of these cases refused point blank to go to a mental hospital on any terms and there was a great need for special hospitals, linked with both general hospitals and mental hospitals, and child guidance clinics, where some of the medical staff should be mental hospital doctors

Dr NOEL HARRIS (London) said that at present there were not enough trained doctors At Woodside Hospital for Functional Nervous Disorders there had recently been a greater demand for beds for the milder psychotics and mixed cases, than for pure psychoneurotics Nursing was of great importance as a bad nurse could do more harm than good The treatment of early cases as inpatients in mental hospitals still presented difficulties, for many years a stigma would remain in the minds of the public Moreover, so long as quiet patients were mixed with excited disturbed patients, it was hopeless to try to treat the early case This depended more on lack of vision than lack of possibility of modifying the situation Facilities for training psychotherapists

were still inadequate, although improving, and hostility between psychiatrists and psychotherapists often had damaging effects on the patient. The public should be educated to demand early treatment and to accept the mental hospital as their friend and helper, instead of fearing it.

Dr. DORIS ODLUM (London and Hove) said that to many people it seemed the psychoneuroses resembled the Loch Ness monster, which was visible only to those who went out to seek it with binoculars and a firm intention of finding something The new psychotherapeutic creed embodied, as articles of faith: "We believe in the psychoneuroses; we believe in the early and preventive treatment of the psychoneuroses and minor psychoses; we believe in the value of child guidance; we believe in outpatient treatment, carried out by an adequately trained staff in suitable surroundings; we believe in inpatient treatment; we believe in the psychosomatic approach and all that this implies" Beyond this point however, all was still in the realms of controversy.

There was no question that the mental hospital had in the past pursued a regrettable policy of isolation In some cases this had almost amounted to purdah, though it was doubtful whether the motive was modesty, self-sufficiency or fear. This attitude had done much to perpetuate the stigma, and contributed to the schism between the so-called psychiatrist and psychotherapist, which, if it persisted, would inevitably wreck the whole mental-hygiene movement The more the mental hospital came into the open, the more it was prepared to give itself to the community and to receive from the community, the greater service would it afford. In connexion with the social reorientation of the patient Dr. Odlum remarked on the important part that was played by Woolworth's stores in reawakening interest in mundane affairs. She agreed with Dr. Flind that very few patients would respond to the more profound types of mental analysis. About 8–10 per cent of her outpatients need a period of inpatient treatment, and would not recover without it In hospital treatment she assessed the importance of the nurse at about 75 per cent and that of the doctor at 25 per cent A stupid nurse could undo in a few hours the psychotherapeutic work of many weeks or even months.

Dr. W. MCCARTAN (Haywards Heath) said that it was difficult to give adequate psychotherapy in a mental hospital. There was a shortage of both trained medical and suitable nursing staff. Of the total admissions in the Brighton area last year sixty-two per cent. were voluntary patients, and for most of them psychotherapy would have been valuable The services of the local public-assistance department should, if sympathetic, be utilised, for social and economic problems played a large part in the causation of mental illness In Brighton the mental-hospital social worker had a desk in the local P.A.C. offices with access to their files and direct contact with the officers

Dr. R SESSIONS HODGE (Crewkerne, Somerset) said that if disease was "an ætiological constellation producing a certain engram" the family doctor was in a position to observe the formation of the constellation, and could act as a field-worker recording the natural history of disease. Outpatient treatment was eminently desirable, as the resocialisation of the patient was more easy if he was not removed from his environment. The stigma of the mental hospital was still very strong in the west of England.

Dr. ROBERT THOMPSON (Armagh, N. Ireland) thought that the wrong turning had been taken in transferring general-hospital methods to mental hospitals and in employing nurses with a general training who did not understand the mental case

Dr. E. F. SKINNER (Sheffield) said that he had treated a number of early and mild psychotics in his own general wards, and thought that they did better there than in a mental hospital. His clinic was known to the students as the Cuckoo Clinic, but they all came to it

Dr. GORDON MASEFIELD (Brentwood, Essex) believed that the mental hospital, properly run, was the ideal place for the early case, but he agreed that there must be proper classification and segregation of the noisy from the quiet, sensible cases. The special hospitals advocated would cut out the admission units in the mental hospitals. It was wrong to speak of the stigma, or to admit that any existed.

Dr. K. C BAILEY (Warlingham) said there were not enough assistant medical officers in mental hospitals to undertake psychotherapy. If the medical profession did not supply the need, non-medical people would take it on

Dr W. C. M. SCOTT (London) said there was as much difference between superficial and deep psychotherapy, or what he would call minor and major psychotherapy, as between opening a boil and brain surgery. The failures of analysis needed investigating, but the failures of the superficial type of psychotherapy needed investigating also.

Dr. HAROLD PALMER (London) said that in other countries—for example, at the Pennsylvania Institute, Philadelphia—patients could be admitted for about three weeks for investigation and treatment; this was valuable for the patient who could not afford to leave his work for a long period He strongly supported the proposal to develop special hospitals for early cases; he would be utterly opposed to any of his relatives going to a mental hospital.

The PRESIDENT did not agree with Dr Gordon Masefield that we ought not to admit the existence of the stigma It was only by facing the realities of the situation that we could hope to deal with it in a constructive manner.

Sir HUBERT BOND (London) concluded the discussion by saying that he thought it would prove to be the most far-reaching of any that had ever taken place at a meeting of the association.

Psychotherapy and the Skin

Dr. TWISTON DAVIES (Brighton) said that there were few cases of skin disease in which the psychological specialist could not help. Even such conditions as alopecia areata had a strong psychological factor Probably it was due to a specific microbic infection, but a state of psychological instability would produce a lowered resistance. He and Dr. Hingston had investigated several such cases together.

Dr. LAMORNA HINGSTON (Hove) said her investigations in the dermatological department had led her to believe that many dermatoses represented a psychosomatic reaction, indicating anxiety in certain personality types, mostly the cycloid type. They represented a substitute for repressions.

Sir LAURENCE BROCK (chairman of the Board of Control) said he had noticed that psoriasis was exacerbated by acute anxiety or overstrain He suggested that mental stress could upset metabolism

(To be continued)

REVIEWS AND NOTICES OF BOOKS

Silicosis and Asbestosis

By Various Authors Edited by A. J Lanza, M D , assistant medical director, Metropolitan Life Insurance Company, chairman of industrial hygiene committee of the New York Tuberculosis and Health Association London Humphrey Milford, Oxford University Press 1938 Pp 439 25s

In the last ten years much work has been done on silicosis and asbestosis but in spite of this it is still difficult to answer many apparently simple points about these two diseases Thus, it is still disputed whether free silica or siliciate causes silicosis, and again the mechanism by which active dust particles set up fibrotic changes in the lungs is not definitely known Indeed in some circles the entity of silicosis as a disease separate from tuberculosis is challenged We welcome therefore a book by acknowledged experts

A useful chapter on the history of silicosis and asbestosis is followed by one on their ætiology, symptoms and diagnosis Silicosis is defined as "a disease due to breathing air containing silica (SiO_2), characterized anatomically by generalized fibrotic changes and the development of miliary nodulation in both lungs, and clinically by shortness of breath, decreased chest expansion, lessened capacity for work, absence of fever, increased susceptibility to tuberculosis, and by characteristic X Ray findings" —a definition formulated by the committee on pneumoconiosis of the industrial hygiene section of the American Public Health Association It is accepted by the authors that the cause of silicosis is silica or quartz, although other dusts may produce definite pulmonary fibroses The findings of a number of committees of inquiry on the pneumoconioses are quoted at length, often without comment In regard to what are called safe concentrations of dust in various industries, it is said that atmospheric concentrations of silica or asbestos dust, which may have proved incapable of producing pneumoconiosis in one industry, may not necessarily be harmless in another Therefore no universal standard of permissible dust concentration can be set up at the present time This is a wise attitude to adopt, particularly when such standards as have been laid down disregard the important factor of individual susceptibility to silica or asbestos dust

The chapter on X ray diagnosis is the longest in the book and could with advantage have been made much shorter, in it E P Pendergrass has not limited himself to the X ray appearances, but deals with subjects which should have come under the survey of other contributors He does however include an excellent section on the X ray picture of the normal lung correlated with anatomical studies S Rood and asbestosis is concise, clear and complete The experimental pathology of silicosis and asbestosis is dealt with by Leroy U Gardner in a fascinating manner E L Middleton discusses ably the complicated occupational, preventive and legislative aspects of silicosis and asbestosis in Great Britain, and A J Lanza presents a similar picture of the position in the United States For the sake of completeness chapters on the preventive and legislative aspects of the pneumoconioses in South Africa, Australia and other countries might with advantage have been included

The editor and his contributors are to be congratulated on the successful production of this important book They have carved out of the chaotic mass of silicosis literature a form which can be appreciated and perhaps understood by all workers in the field of industrial pulmonary diseases

Clinical Pathology

(4th ed) By P N Panton, M.B Camb , clinical pathologist to the London Hospital, and J R. Marrack, M D Camb , professor of chemical pathology in the University of London, and chemical pathologist to the hospital London · J and A. Churchill 1939 Pp 502 10s

It is no mean feat to crowd, as this book does, almost the whole of clinical pathology including histology and media making into 502 pages But the book loses a little by its excessive conciseness For example, although liver therapy by mouth is mentioned, there is no reference to the valuable extracts now given by injection In discussing the use of the colorimeter, the increased accuracy to be obtained with the use of colour filters is not mentioned, nor does the note on the sedimentation-rate mention the errors due to excess oxalate It would have been helpful if the simpler and quicker methods mostly used for the estimation of sugar and chloride in the cerebrospinal fluid had been described There are also one or two loose statements such as "Into seven large test tubes in a rack put 0 1 c cm of complement in tubes I to IV" But there is no cause for major criticism, and many practical points are brought out here which are omitted from larger works The book will be a valuable addition to the library of any clinical laboratory

Guiding Principles for Studies on the Nutrition of Populations

By Dr E J Bigwood, professor at the University of Brussels London Allen and Unwin (League of Nations Publications Department) 1939 Pp 281 6s

The whole subject of how to assess the nutrition of people is clearly, concisely, and adequately covered in this book, and although the author is critical and sceptical, he none the less is convinced of the possibility of the task The author wisely states that the absolute minimum period of investigation for individual households is one week Wherever possible this period should be exceeded With the household-book method it is advisable to extend the period to about a month He makes clear the often forgotten distinction between two categories of waste—household waste and physiological waste The former includes everything which escapes consumption, the latter consists of substances eliminated by the organism as the result of imperfect utilisation on its part The importance of defining conditions of calculation in making a physiological analysis of nutrition surveys and of calculating the ratio of animal proteins to the total proteins are emphasised The international units of the vitamins are given and their relations to other superseded units, and the present day assessment of the units is described Prof Bigwood assesses the vitamin B_1 requirement of the adult at 300 I U per day, of the child of preschool age at 200 to 250 I U per day and of an infant at 10 to 15 I U per 100 calories This will cause some heart burnings among the B_1 fanatics There is an admirable chapter on statistics

and no-one after reading it need be frightened by the jargon of the statistician

The rest of the book deals with the methods of discovering at the earliest possible moment the effects of the "highly unsatisfactory state of nutrition of a large part of the population of various countries," described in the Health Section (League of Nations) Report of 1932 The author believes that simple height and weight measurements *may* have some use in assessing nutrition, but discards all the more complicated indices of Quetelet, Manouvrier, Pirquet and others. He has little use for the subjective scales of assessment of nutrition utilised by the British Board of Education and the Ministry of Health, and very naturally quotes R. H. Jones's statistical attack on this method of assessment. The author inclines to the accurately measurable signs of deficiency as a means of assessment. He would use photometry for vitamin-A deficiency, the phosphatase test for vitamin-D deficiency and either the vascular resistance or the body saturation test for vitamin C He admits that these detailed investigations take much more time and skill than the nutrition surveys, and concludes that it will be necessary to combine dietary surveys and inquiries into the state of nutrition covering the same population groups

Most nutritional workers will agree with his preference for estimations of the lack of the vitamins, for while it is rare to find a lack of calories and proteins with a first-class supply of the protective foods, it is common to find a satisfactory supply of calories and proteins with an almost total lack of the protective foods

To everyone interested in research in, or in the teaching of, dietetics this excellent book is indispensable

Frustration and Aggression

By JOHN DOLLARD, LEONARD W. DOOB, NEAL E. MILLER, O. H. MOWRER, ROBERT R. SEARS. London: Humphrey Milford, Oxford University Press. 1939. Pp. 190. 9*s*.

It is a pleasure to find clinical psychology applied to social issues in a genuinely scientific way. The authors of this book, which is published in America for the Institute of Human Relations, take as their fundamental working hypothesis the relatively familiar theory that aggression is due to frustration and then proceed to a systematic study of aggressive behaviour to see how far this theory will require modification. An integral part of their theory is the view that frustration must always be considered in relation to instigation—namely, to what extent a desire has been stimulated. Thus not being able to afford a wireless set is a condition much more frustrating to an Englishman than to an Eskimo.

The severe frustrations imposed on children from their earliest years, the special frustrations of adolescence, and the frustration inevitable in a social life whatever the form of government are all considered scientifically and in detail with much reference to conditions in the more primitive societies. The authors make tentative attempts to correlate these frustrations with outbursts of aggression In this they make use of such concepts of clinical psychology as repression, displacement, self-frustration and self-aggression In a particularly interesting chapter they review the many and diverse factors found to correlate with criminality (itself a form of aggression), and make out a good case for regarding them all as indicating a higher degree of frustration than the average.

There is one type of aggression which is not discussed and which will probably need consideration in further studies. This is the tendency to see internal frustrating forces as external—to project internal frustrations on external persons or institutions and attack them there. This seems to be the chief omission in a book whose merit lies in its insistence on an economy of theory and in its serious and mostly successful attempts to group and explain a great variety of apparently discrete phenomena.

Forensic Medicine

(3rd ed.) By DOUGLAS J. A. KERR, M.D. Edin., F.R.C.P.E., D.P.H., lecturer on forensic medicine in the school of medicine of the Royal Colleges, Edinburgh. London: A. and C. Black. 1939 Pp. 331. 15*s*.

THE secret of this book's success with the student is easy. It is lucid, confines itself to matters of practical value, and is magnificently illustrated. Furthermore, it is unburdened with profuse or aged references and is fresh both in matter and style. The author has the knack of presenting essentials in a few simple phrases, and he outlines the law's relations to medicine in such clear perspective that forensic medicine begins to look like the mere application of common sense.

In this edition the book has been improved without lengthening it appreciably Changes necessitated by alterations in the law such as the Infanticide Act 1938, or introducing new matter as under the Matrimonial Causes Act 1937, have been made, the section on professional secrecy has been rewritten, and the entire text has clearly been revised in some detail. A stray error has crept into the table outlining the maturity of the fœtus, where the 5th-month features read in error, the important calcaneus centre is post-dated by two months and there is no mention of other vital ossification centres

The book remains nevertheless a competent and attractive outline of the subject.

Encyclopædia of Sex

By GEORGE RYLEY SCOTT, F.Z.S., F.Ph.S. Eng., F.R.A.I. London: T. Werner Laurie. 1939. Pp. 352. 21*s*.

It was Havelock Ellis, to whom this volume is dedicated, that subjected the manifold expressions of the sexual impulse to an analysis so searching that he can be said to have converted his subject into a science The complexities which he disclosed necessitated an elaboration of the previously somewhat scanty terminology, and the literature of psycho analysis has added many words more Thus encyclopædia is therefore not inopportune, and Mr. Scott has performed his difficult task with skill In a preface he points out that his book, while suffering from the limitations of being a one-man work, also derives certain advantages from its single authorship. The longer articles have a consistency and unity which are absent from a symposium, however skilfully edited.

The contents are arranged in alphabetical order, some of the terms being merely defined as in a dictionary, while others are treated at length. Curiously enough, though archocystocolposyrinx and terms equally unfamiliar are included, the important word sublimation is omitted The author makes no attempt to disguise his personal views: indeed, he sometimes expresses them with almost excessive vigour. But Mr Scott's approach will give offence to nobody except perhaps the advocate of complete sexual liberty.

THE LANCET

LONDON · SATURDAY, JULY 22, 1939

CARBOHYDRATE METABOLISM

No disease has a background more tantalising than that of diabetes mellitus Long before BANTING and BEST made their famous preparation of insulin the importance of this substance was realised and its discovery predicted In the therapeutic field its success was dramatic, yet in spite of his foreknowledge the physiologist had no niche for it as had the astronomer for a new planet or the chemist for a new element Insulin supplied a known deficiency because in its absence the machinery of carbohydrate metabolism laboured painfully and wastefully on the brink of disaster, while in its presence the wheels ran sweetly and without stress, but the deficiency had not been set out in precise terms, and to this day the manner in which insulin performs its miracle is matter for controversy In the meantime much has been learnt and the sum of all this knowledge is set out by Professor HIMSWORTH in his Goulstonian lectures, the last instalment of which appears in our present issue His own work is a worthy link in a chain of important contributions to medicine, typical of the present day, in which the physiological background of therapeutic advance is explored by controlled observations on human subjects, reinforced by laboratory investigation and animal experiment

Let us attempt to set out in a few words the point that has been reached In the absence of the liver, sugar disappears from the blood stream, showing that this organ is responsible for the conversion of the foodstuffs, and if necessary of the tissues of the body, into glucose Perhaps insulin controls its output and diabetes is due to its unchecked activity The liver is a notoriously difficult organ to study experimentally, but there is evidence that in diabetes it is producing more glucose than normally, and it certainly then disobeys its normal rule of curtailing production when the blood-sugar tends to rise in concentration It cannot lightly be dismissed as not guilty On the other hand there is excellent evidence, as HIMSWORTH points out, that in diabetes the peripheral tissues use less glucose than normally Here, so in effect he argues, is a strange coincidence One would expect under-utilisation of glucose by the tissues to relieve the drain on the blood sugar, and therefore the demand on the liver Is it likely that the tissues and the liver should each act abnormally in a direction which increases the blood sugar concentration, thus simultaneously losing its inhibitory effect on hepatic glycogenolysis? The synchronous disintegration of a system in this way is not intellectually satisfying HIMSWORTH's own investigations have led him to a different interpretation He advances the view that the relative inability of the tissues to use glucose in the absence of insulin is at the root of the trouble, the high level of blood-sugar is a physiological adjustment giving the tissues a bigger "head of pressure" of glucose with which to work It is known that this increases their power to make use of it When the adaptive concentration surmounts the renal threshold the output of the liver must increase by leaps and bounds, for it must maintain this concentration and at the same time make good the leakage through the kidneys The evidence for this theory, which has the merit of coherence, is ably presented by HIMSWORTH, though he has yet to find the nature of the stimulus transmitted to the liver from the embarrassed tissues Whatever it is, it must take precedence over the mechanism by which the liver is said to respond correctively to a rise or fall in the actual blood-sugar concentration The careful experiments of SOSKIN and his colleagues purporting to establish such a mechanism fail to exclude the possibility of a "message" direct from the tissues to the liver HIMSWORTH suggests the brain as the most sensitive tissue

Whatever the outcome of this part of the story, it is now certain that the mere presence or absence of insulin is by no means the only thing to be considered The sensitivity of the body to insulin can alter considerably, it varies, for instance, with the carbohydrate content of the diet This can only mean a second variable factor at work, the abnormal operation of which might well result in a pathological insensitivity to insulin and a different type of diabetes. It is now commonly accepted that an insulin insensitive kind of diabetes has been established, HIMSWORTH, who has himself made large contributions to the study of insulin sensitivity, claims to be able to distinguish it by a clinical test from that due to insulin lack The nature of the second factor is not quite certain, indeed, it may not be a single entity In theory, it could be something which aids or something which impedes the action of insulin, the evidence for its presence being merely the power it has of influencing the latter In practice, our thoughts fly to the anterior lobe of the pituitary gland, which has become so important in carbohydrate metabolism since HOUSSAY showed how its removal ameliorates experimental pancreatic diabetes in animals Here, however, we find ourselves confronted with problems no less baffling than those relating to insulin itself Does the anterior pituitary act on the liver, the peripheral tissues, or both? What is its exact relation to insulin? HIMSWORTH stresses the importance of the evidence associating it with the liver in the production of glucose from non-carbohydrate sources In its absence, any extra ordinary demand by the tissues for glucose is not met, and when it is removed from the diabetic dog the compensatory rise of blood sugar concentration fails to take place

It has been shown that pituitary extracts will cause glycosuria, YOUNG has produced permanent diabetes in dogs by a course of anterior pituitary

injections. The pancreatic lesions found in these cases might be explained by overaction of the islets in response to the excessive mobilisation of glucose by the liver, but YOUNG has also found a pituitary fraction which antagonises insulin while having no influence on blood-sugar level. This apparent versatility on the part of the anterior pituitary is a deterrent to rash speculation, though fortunately it introduces no incongruities. LONG and his colleagues have implicated the suprarenal cortex in the story, and so discoveries follow each other faster than they can be assimilated It is too much to expect of any modern theory that it should accommodate all the known facts, but sooner or later gross surprises must become fewer, and the field be worked over again carefully to test the more comprehensive hypotheses. Of these the one put forward by Professor HIMSWORTH must rank among the most important.

SPIROCHÆTE AND WASSERMANN REACTION

THE significance of the Wassermann reaction has often been questioned on the ground that it is not a specific test since the reagin (antigen) used is as a rule an alcoholic extract of heart muscle and not the *Treponema pallidum*. Modern improvements in the technique of spirochæte cultivation have made it possible to investigate this criticism from a new angle, and the work done in the last two years by BECK[1] at the London County Council laboratories provides a more firm basis for argument. Employing a standard Wassermann technique he tested 1100 sera in parallel, using as a reagin in the one case an alcoholic extract of heart muscle and in the other a carbol-saline suspension of five strains of cultured spirochætes. Out of 542 sera from known syphilitic patients the two reactions agreed in 80 6 per cent. Of the remainder, 14 8 per cent. gave a positive spirochætal complement-fixation (Sp C.F.) reaction with a negative Wassermann reaction, and 4·6 per cent a negative Sp C F. reaction with a positive Wassermann reaction. The control group of 496 non-syphilitic sera gave a positive Wassermann reaction in 1·2 per cent and a positive Sp C F. reaction in 1 6 per cent On comparing these findings with the clinical histories of the patients it was found that the Sp.C.F. reaction was the more sensitive in all stages of syphilis and especially so in the late latent stage While admitting the doubtful identity of the spirochætes from which the antigen of the Sp.C.F. reaction was obtained it seems clear from their practical value in the Wassermann reaction that a definite antigenic relationship exists between them and the *Tr. pallidum*. This view is also supported by the experimental evidence of their specific behaviour.

In experiments designed to show the specificity of the Sp.C.F. reaction the spirochætes were grown in a medium containing no liver, thus avoiding any non-specific antigenic action due to liver contaminants. Of the two non-spirochætal antigens used, negative reactions were obtained with 48 sera (21 of which were positive with the Sp.C F. reaction) when an antigen prepared from *Corynebacterium diphtheriæ* was used Using a *Leptospira icterohæmorrhagiæ* antigen, only 1 weakly positive result was obtained with 102 sera, 45 of which were positive to the Sp C F. reaction. With the closely related *Spirochæta dentium* a definite antigenic reaction with syphilitic sera was obtained A total of 773 sera were tested in parallel using the Sp.C F. reaction antigen and one made from the *Sp. dentium*. Of 407 syphilitic sera tested, 42·7 per cent reacted positively and 27·8 per cent. negatively to both antigens, while 29 5 per cent. reacted positively with the Sp.C F. reaction but negatively with *Sp dentium* antigen. Thus of the total of 72·2 per cent positive sera recorded by the Sp C.F. reaction 59·2 per cent. were also positive to *Sp. dentium* antigen At the same time, the latter antigen showed a tendency to give non-specific positive reactions (4 4 per cent) with the 366 non-syphilitic control sera. From these results an antigen prepared from the *Sp. dentium*, though much less sensitive than that used in the Sp C F. reaction, appears to have a definite antigenic relationship to the *Tr. pallidum*.

On comparing the antigenic value of the five strains of cultured spirochætes used in this investigation, they were found to be approximately equal in sensitivity and specificity with the exception of the *Sp dentium* which was definitely less so in both respects The serological structure of these five strains of spirochætes was demonstrated by means of cross-agglutination, complement-fixation and absorption tests with antisera prepared against them It appeared that there were four types present of which the *Sp. dentium* represented one. By similar tests parallel serological differences were found to exist in the antibody structure of the patients' sera reacting with these strains. Thus it was found possible to separate the antibody reacting with the standard Wassermann antigen (extract of heart muscle) from the spirochætal antibodies, and also to differentiate between each of the spirochætal antibodies themselves. During this part of the investigation it was found that with a syphilitic serum a positive reaction obtained with a *Sp dentium* antigen was abolished by absorption of the antibody by any of the other spirochæte strains. The converse however did not hold. At the same time, absorption by non-spirochætal antigen (*C diphtheriæ* and *Lept. icterohæmorrhagiæ*) did not suppress the positive reaction with syphilitic sera given by the *Sp. dentium* antigen. It is therefore probable that some specific factor is at work when a *Sp. dentium* antigen reacts with syphilitic serum. The next step was to show the nature of the spirochætal antigen. An alcoholic extract of spirochætes, a carbol-saline suspension of whole spirochætes, and the Wassermann antigen (heart extract) were added to separate portions of syphilitic sera and subsequently tested against these antigens. It was found that on mixing the positive syphilitic serum with the alcoholic extract of spirochætes or the Wassermann antigen the homologous antibodies were removed and there was no fixation of complement when using these

1. Beck, A., *J Hyg., Camb* May, 1939, p 298

extracts as antigens, but that when a carbol-saline suspension of whole spirochætes was used as an antigen against the same sera the result was positive A parallel result was obtained if the sera were mixed with the carbol saline suspension of spirochætes and then tested against the three antigens BECK concludes that the spirochæte contains two antigens—namely, the "ubiquitous" lipoid antigen of heart muscle and other tissues, and a specific antigen which is not extracted by alcohol in sufficient quantities to be shown by absorption tests It was found impossible to isolate this specific antigen until the method of tryptic digestion used by RAISTRICK and TOPLEY in the preparation of paratyphoid antigens was adopted A fraction (termed F68) was obtained from the spirochætes and this reacted strongly with antispirochætal sera but not with syphilitic sera BECK suggests that a combination of the F68 fraction with a non specific "intensifier" of lipoid nature is necessary to bring about reactivation, since an extract of the trypsin-digested spirochætes is actively antigenic before the addition of the alcohol necessary to precipitate the F68 factor It would be interesting to know if cholesterin would act as a reactivator of this antigenic fraction

This work will undoubtedly stimulate fresh interest, and it makes still more obvious the need for a way of isolating, cultivating and identifying the *Tr pallidum* beyond all question It should then be possible not only to produce a truly specific Wassermann reaction but also to gain some understanding of the rôle of the alcoholic extract of heart muscle in the present Wassermann technique

DIPHTHERIA IMMUNISATION IN GUERNSEY

A SCHEME of immunisation against diphtheria has been introduced this year in the island of Guernsey (including the islands of Herm and Jethou), the fruits of which will certainly be examined carefully in time to come In studying the scheme, and its results in the future, the island's recent history of diphtheria is both relevant and interesting The reports of the late medical officer of health, Dr H D BISHOP, show that it experienced a prolonged epidemic in the years following the late war This was succeeded by a period of slowly declining incidence, until from 1932 to 1936 the disease was almost absent from the island Among some 10,000 children below the age of fifteen only 22 cases were notified during these five years Under such conditions a susceptible population was built up and a fresh epidemic naturally developed In 1937 some 60 cases were registered, and in 1938 the epidemic reached an extremely high level, unprecedented in the island's records of the present century, nearly 500 cases being reported with 14 deaths

To this unfortunate experience the board of health responded with a compulsory scheme for inoculation, which was accepted by States early in 1938 and confirmed by Order in Council in March, 1939 In the interval caused by the necessary legal procedure free inoculation was offered by Dr R W REVELL, the present medical officer, to those ready to take advantage of it, and by the end of 1938 as many as 3500 children had been immunised The compulsory order of 1939 applies to all children who were between the ages of two and ten years on April 15 last, and in future years to all children as they reach the age of two In course of time, therefore, virtually the whole population will have been inoculated in early childhood So far some 6000 inoculations have been performed, comprising nearly all the children between two and ten, with volunteers of other ages The prophylactic chosen is alum-precipitated toxoid (A P T), which is being given in two doses at an interval of not less than 13 days nor more than 28 days, the first dose being 0·2–0·5 c.cm., at the discretion of the medical practitioner, and the second dose 0·5 c.cm Inoculation is performed by the medical practitioners of the island, as appointed for the purpose by the States board of health, supplies of A P T being provided to them free of charge The practitioners are paid half a crown in respect of each administration—i.e., five shillings per completed inoculation—and are required to return details of each inoculation on prescribed forms From these records it will be possible to gather valuable information as the years pass, relating to the children's ages when inoculated and their subsequent history as regards diphtheria According to last year's records there were 10 cases of mild type among some 3000 immunised children It is also reported that there was a rapid fall in the general incidence of the disease towards the end of January, 1939—some months earlier than the expected seasonal decline—and at the present time only an occasional case is developing The main interest of the scheme must lie, however, in the future, over the next ten years or so

It is notoriously difficult to disentangle cause and effect in inoculating during an epidemic prevalence, and less obvious problems of the duration of exposure to risk complicate simple comparisons between the experiences of the inoculated and uninoculated In most places, too, it is hard to relate the secular trend of diphtheria to the incidence of inoculation, for the latter tends to fall, under a voluntary scheme, when the disease and the fear it engenders are absent, and thus a new susceptible population accrues Such a falling-back will not take place in Guernsey with its inoculation year by year of all children as they reach the age of two, and the crucial evidence will be the absence of the epidemics that might be expected to recur at intervals in its small and partially isolated community Voluntary immunisation might well, and doubtless will, be offered at a rather earlier age than two—towards the end of the first year of life—and also, at present, to children over ten, the interval between doses might, perhaps, on the available evidence, be made to approximate to the higher limit of four weeks rather than to the lower limit of two These, however, are relatively minor points On the general issue, Dr REVELL and the Guernsey authorities are to be congratulated on the firm action they are taking to eradicate diphtheria in epidemic form from the island

ANNOTATIONS

THE GLUTAMIC ACID OF TUMOUR PROTEINS

Kögl and Erxleben [1] lately presented evidence that some of the amino-acids of malignant-tumour proteins are partially racemised and that the effect is greatest in the case of glutamic acid. These findings suggested an essential difference between the proteins of normal and of malignant tissues and enabled hypotheses to be put forward regarding the mechanism of malignant change Special importance therefore attaches to a communication from Chibnall and his collaborators,[2] who have sought to confirm the new observations. They have hydrolysed proteins derived from Crocker mouse sarcomas, a human carcinoma of the bronchus and a human carcinoma from the neck, and have separated the dicarboxylic-acid fraction by a modification of the calcium-salt method of Foreman; and in each case the glutamic-acid hydrochloride ultimately isolated in good yield showed the optical rotation characteristic of the usual l(+) glutamic-acid hydrochloride. To these English findings Kögl and Erxleben reply [3] that the method of fractionation employed by Chibnall may not lead to the eventual isolation of partially racemised glutamic-acid hydrochloride if this is present. They emphasise that there is an essential difference in the solubilities of the two forms of glutamic acid, both as the calcium salt and as the hydrochloride, and state that the *d*-form has a greater solubility than the *l*-form. Consequently they consider that only the *l*-form would have been isolated under the conditions used by the London investigators. In an attempt to confirm this, they added known amounts of *d*-glutamic acid to protein hydrolysates from normal tissues—which should contain only *l*-glutamic acid—the mixture being then submitted to fractionation via the calcium salts The glutamic-acid hydrochloride they isolated in this way had the normal rotation Kögl and Erxleben further say that they have now succeeded in isolating *d*-glutamic acid itself from the partially racemised hydrochlorides obtained from Brown-Pearce tumour, which indicates that the low rotation of these latter products cannot have been due to the presence of impurities with a rotation of the opposite sign A further statement from Chibnall and his colleagues will be awaited with interest.

VASODILATOR DRUGS IN RAYNAUD'S DISEASE

THE knowledge that Raynaud's disease results from a spasm of the digital arteries encourages the constant hope that a suitable vasodilator drug may be found to relieve it The perfect drug for the purpose would maintain an adequate blood-supply to the hands for many hours even though they were meanwhile exposed to cold; it would have no undesirable effects on other parts of the body, and it would be easy to administer. Nitrites have too transitory an action, as also have the acetylcholine derivatives unless administered by the cumbersome and somewhat difficult method of electrolysis; and recently [4] papaverine hydrochloride has been advocated, though to be effective it must be injected intravenously The value of all such complicated forms of treatment is questionable, because the patient is apt to decide that she prefers cold fingers to a very frequent attendance on her doctor for intravenous or electrical treatment. It has also been shown [5] that the simple procedure of warming the body—for example, in a hot bath—increases blood-flow in the hands just as effectively as iontophoresis with drugs The hot bath serves at least as a convenient control in judging the value of the newer, more complicated and expensive methods.

"HEALTH FOR 7,500,000 PEOPLE"

New York city is the largest health unit in the world, for though England's metropolis contains a somewhat larger population its health services are divided whereas those of Greater New York were unified by charter in 1901, when they were placed under a board of health consisting at present of seven members, five of whom are medical men. The American system of public-health administration differs considerably from ours and formerly was subject to political influences, but of recent years the system has been made much more stable and in New York especially the machinery is now as efficient as any in the world. A full account of the method of health government is given in the report of the commissioner, Dr. John L. Rice, for 1937, which contains a review of progress over the five years 1934–38. During this period the cost of the service has varied from 4¼ to 5 million dollars annually, but the New York citizen does not grudge the money, and since La Guardia has been mayor the success of the department has been so great as to bring conviction that money spent on health is soundly invested The death-rate of New York in 1937 was 10·4; the infantile mortality dropped steadily from 53 in 1933 to 44 in 1937, tuberculosis mortality (per 100,000) fell from 64 to 57, and maternal mortality (per 1000 births) from 6 to 4 The last rate is computed somewhat differently from ours and the New York figure of 4 is about equal to a London rate of 3. The five-year period has been one of rapid development in the health programme; the city is divided into 30 districts of which, at the end of 1937, two-thirds were completely organised. Though the Americans have a legal health code even more complicated than ours, they use it less. "Modern public-health administrations," Dr. Rice remarks, "makes relatively little use of police measures and carries on most of its work through health education." New York in fact claims to be the pioneer of educating people to look after their own health rather than trying to enforce health by legislation—and it may be granted that its health propaganda has been remarkably successful Two points in the American system which are superior to ours are the efficiency of the laboratories for clinical diagnosis, especially in connexion with the differentiation of types of pneumococcus, and the length of the list of diseases compulsorily notifiable. Three groups of diseases trouble New York more severely than they do London—the pneumonias, diabetes, and heart disease in early middle age. In 1937 pneumonia was charged with 6504 deaths in New York against London's 3477 and diabetes with 2669 against London's 655. In New York all fœtal deaths are reportable; of 4802 abortions notified to the department in 1937 some 25 per cent were embryos

of less than 20-weeks gestation, as however 83 per cent of all abortions are reported from hospitals it is probable that many early abortions are missed

MORE PAY FOR MENTAL NURSES

THE London County Council has decided to increase the pay of both male and female nurses in its mental hospitals, and to increase holidays Male hospital assistants and male nurses of all grades between staff nurse and head nurse are to be granted an increase of 3s a week, and an increase of 2s a week will be granted to women hospital assistants and women nurses between staff nurse and sister The annual leave for head nurses and sisters is to be increased to 4 weeks—one week more than staff under their immediate control The additional expenditure will be £10,580 in 1939-40 £22,835 in 1940-41 and about £19,313 in each subsequent year These increases are fully justified The apparently lavish pay of the female mental staff nurse of 46s a week suffers a large compulsory deduction for board and lodging, and the advent of women social workers and occupational therapists on professional salaries has caused much heart burning among mental nurses The council's action should remove grumbles and help recruitment

PULSUS ALTERNANS

OF late years little attention has been paid to pulsus alternans, either as a guide to prognosis or as a guide to the mechanism of heart failure, yet it has never been adequately explained. The earlier observations of Wenckebach [1] suggested that at the end of the smaller beat blood remains in the heart, so that the diastolic filling and the initial tension of the fibres at the beginning of the next beat are greater, and therefore the heart—working at a better mechanical advantage—empties more completely At the next beat diastolic filling and initial tension are smaller and a feebler beat results More recently Green [2] has shown that derangement of one portion of the myocardium may give rise to alternation With an electromagnetic clamp he was able to exclude a main coronary artery of the dog for part of the cardiac cycle so that the blood supply was impaired though not entirely suppressed In a number of hearts so treated alternation took place, and by means of optical myocardiograms it was shown that during the smaller beats the affected areas contracted only slightly if at all. Thus it seems possible that alternation in the mammalian heart may arise from a relative failure of the whole or a portion of the heart to contract at alternate beats

In using pulsus alternans for prognosis the first essential is to be able to decide when it is present Only in cases where it is pronounced can it be recognised by palpation of the radial pulse Though it becomes apparent when the radial pulse is graphically recorded, this entails the use of apparatus to which few are accustomed, and actually the alternation may be equally well discovered by careful attention when taking the blood pressure As the cuff pressure is being lowered, there is a stage at which only each alternate beat can force its way through, then when the pressure is further lowered to the second systolic level all beats come through, so that the cardiac rate appears to be abruptly doubled The degree of alternation may be expressed as the difference between the two levels, in millimetres of mercury Occasionally the alternation only appears for a few beats after an extra systole or when the heart is beating rapidly Occasionally it may be seen in the electrocardiogram and still more rarely it appears in the electrocardiogram though it cannot be detected in the pulse [3] Pulsus alternans is to be distinguished from alternate extra systoles by the fact that in alternation the beats are regular, whereas in extra systoles a longer pause follows the shorter beat White [4] found the condition in a third of all cases showing any degree of cardiac failure and in 71 of 300 cases with cardiac or cardiorenal disease From the standpoint of prognosis, he said, patients with pulsus alternans should be divided into two groups The first consists of those in whom it is associated with a very rapid heart rate (e.g., in paroxysmal tachycardia), in this group its presence does not seem to affect the prognosis The second group is that in which the heart rate is relatively slow, and here it is of serious significance Thompson and Levine [5] observed over a twelve year period 117 patients with constant pulsus alternans, the date of death of 71 being known Of this series the 50 males lived an average of seventeen months after the detection of the abnormality, and the females eight and a half months Only 5 of the 71 patients were under forty and in them the average duration of life was only six months after the detection of the abnormality, generally speaking it was found that the seriousness of the sign decreased with the increase in age of the person in whom it was detected

Such an easily elicited and important sign of failure of the left ventricle should be carefully looked for in all cases of hypertensive heart disease, coronary thrombosis and luetic aortitis

BEDBUGS IN SHIPS

THE Association of Port Health Authorities of the British Isles has issued [6] a pamphlet on the prevention of infestation of ships by bedbugs, illustrated with a coloured plate reproduced from Memo 180 Med of the Ministry of Health Bedbugs can be a worse nuisance on board than they are ashore, but owing to the confined nature of cabins infestation is easier to prevent Introduction can only occur at ports, mainly through the clothing of the crew, inspection and personal cleanliness can prevent bugs from reaching the quarters. Even should they do so, infestation is unlikely to result if the quarters are kept scrupulously clean and if attention is paid to nooks and crannies which might afford suitable cover This is less difficult in ships than it is in houses Should infestation occur from neglect of the cleanliness requisite to prevent it, disinfestation must be adopted The pamphlet recommends fumigation with sulphur dioxide which is safe but not always efficient, or with hydrogen cyanide which is highly dangerous but efficient if carried out properly Fumigation with cyanide is only practicable in port in a ship temporarily laid up and carried out by experts An old boat badly infested may be as impossible to free as is an old house, but even a reasonable degree of cleanliness together with attack on the first sign of infestation should be sufficient to assure freedom The moral is clear enough As with all insect pests, it is comparatively easy to prevent bugs from getting a foothold, but once they establish themselves they are

exceedingly difficult to exterminate. The new agreement (July 1) between shippers and seamen to coöperate in ensuring the cleanliness of crews' quarters should go a long way towards ridding the merchant service of a preventable evil.

TREATMENT OF ACUTE CHOLECYSTITIS

THE best time for operation in acute cholecystitis is debated by Ehnmark in a monograph entitled the gall-stone disease[1] Surveying the fluctuation of surgical opinion, he shows how at one time acute cholecystitis has been treated as an urgent surgical emergency, while at others operation has been postponed until the acute symptoms have subsided As early as 1903 Riedel advised operation within twenty-four hours of the onset of the attack; by 1920 operation during the interval was widely supported, both in this country and in Germany; while from that date onwards an increasing number of surgeons in German and in Scandinavian countries, Ehnmark finds, insisted on surgical treatment in the acute stage Still later more support has been shown for operation after subsidence of the attack, but in Scandinavia opinion seems to have remained very much divided The one item on which Ehnmark finds general agreement is that grave cases, with pronounced peritoneal irritation or with perforation, ought to have immediate operation unless the patient's condition is hopeless For cases of less severity there are at present three opinions operate at once, as for appendicitis; wait a few days, till the most acute symptoms have subsided; operate only after the attack has passed, when the temperature and pulse are normal, the abdominal tenderness has gone, and the patient is eating and is feeling pretty well Ehnmark thinks that surgeons who advocate postponement till the morbid process is at an end are offering a theoretical opinion on which they could not act in practice To obtain complete healing takes so long—several weeks or months—that the patients would be discharged from hospital, and would be unlikely to consent to readmission at the desired time He himself proposes the term "clinical interval" to designate the stage of the disease in which temperature has become normal, abdominal symptoms and possible jaundice have disappeared, and the patient may be allowed out of bed From his own careful analysis of 257 operations for acute cholecystitis performed in the surgical clinic of the University of Uppsala, he is convinced that operation is best performed in this clinical interval

The most significant feature of the Uppsala figures is the drop in operative mortality in the cases treated during the last period under survey—namely, 1932–35. In the first two periods (1922–27 and 1928–31) it is about equally high (14 8 and 13 3 per cent respectively), but in the third it has dropped to 3 5 per cent Having tried to examine all the factors that could have contributed to this result Ehnmark is persuaded that the sole significant change was that during the years 1932–35 the patients were operated on in a later stage of the disease, or after a longer time in hospital Since 1932 almost all the moderately severe cases have been operated on in the clinical interval, whereas before that date most of them were operated on while the attack was in progress Even of the severe cases, less than half have, since 1932, had the operation in the acute stage, whereas in 1922–31 it was the exception to wait

Severe acute cholecystitis Ehnmark regards as a disease with a high mortality In the worst cases, although the risk is great, he thinks immediate operation is right, unless the condition is quite hopeless. Cholecystostomy is then his choice In other cases it is reasonable to expect spontaneous improvement, and cholecystectomy undertaken during the "clinical interval" bears, in his opinion, a comparatively small risk It is not the practice in Uppsala to operate for the first attack, unless life is in danger.

DEATH OF A GORILLA

"Moina" only survived the death of her spouse "Mok" for about seventeen months She refused food, lost interest in life, and became savage with her keepers when roused In May she developed cracks and abrasions on her hands and feet which she picked and gnawed until they became large septic sores; these it was impossible to dress or treat otherwise than by squirting antiseptics on them through the bars of her den Finally gangrene of the right foot and leg developed and she died of sepsis and toxæmia from the gangrenous leg At the post-mortem examination Colonel A. E Hamerton, pathologist to the Zoological Society, could find no pathological lesions others than those associated with septicæmia Histological examination of the peripheral arteries and nerves has not so far revealed anything to account for the primary lesions on hands and feet These, he thinks, were probably traumatic in origin

CLINICAL APPLICATIONS OF TESTOSTERONE

THE last few months have seen several attempts, especially in the United States, to multiply the uses of testosterone In view of the resemblance between many androgens and progesterone, Rubinstein and Abarbanel[1] have tried testosterone propionate for dysmenorrhœa, and report complete relief in 16 out of 26 cases, and partial relief in 4 The patients that benefited were those with "essential" dysmenorrhœa, attributed largely to hormonal imbalance, and in those with structural abnormalities of uterus or tubes the symptoms were sometimes made worse The remedy works, it is supposed, by depressing pituitary gonadotrophic secretion, reducing the formation of œstrogen, and favouring luteinisation and the progestational response of the myometrium

In a different field Edwards, Hamilton and Duntley[2] claim to have used testosterone propionate with success in the treatment of organic disease of the peripheral vessels This use of the hormone was first suggested by its general vascular effect on the skin—arterialisation in such regions as the head palms and soles, as revealed by a recording spectrophotometer—and benefit is reported in three men with thrombo-angiitis obliterans and in four cases of arteriosclerosis In reviewing the undisputed clinical uses of testosterone, Kearns[3] concludes, first, that it is an effective means of substitution therapy in castrated or cryptorchid patients, and secondly, that injunction of free testosterone in a greaseless base is as effective as intramuscular injection of the propionate The injunction of male hormone which has been studied in this country by Foss[4] is deemed

useful because it imitates the steady, continuous androgenic action of normal testes, and because it obviates frequent contact with the physician

THE HANDS OF THE AMATEUR GARDENER

THE Manchester city coroner has been warning gardeners of the danger of wounds contaminated with manured soil. The case that inspired his comments was that of a solicitor's cashier who pricked his finger while tying up roses and died soon afterwards from infection of the finger. Scratches and pricks of this kind are almost inseparable from gardening, and the question is how far these wounds must be taken seriously. In his first acquaintance with the casualty department of his hospital, the student learns that wounds contaminated with soil are regarded with concern because of the possibility of infection with the organisms of gas gangrene or with tetanus spores that will become active in damaged tissues. Wounds severe enough to reach the casualty department receive such thorough treatment that the incidence of tetanus there must be very low, but minor lesions are a different matter. The horny hands of the professional gardener are unlikely to be infected by trivial injury such as punctures from thorns, but the week-end gardener has a readily vulnerable epidermis, and should his wound become septic or show necrosis tetanus becomes a very real danger. The perils of manured soil should be as well known to the gardening public as to the doctor, and though it is too much to expect the amateur gardener to rush to the doctor with every lesion, he should know of the special risk from penetrating wounds, and the advantage of antiseptic treatment of those that are more superficial.

LONDON HOSPITALS IN WAR-TIME

ON June 30 a letter appeared in the press signed by twelve chairmen and treasurers of London teaching hospitals, who complained that lack of a director, charged with full responsibility for the war-time organisation of the London hospitals, has meant that there is at the moment nothing more than an outline scheme on paper. The work of the sectors, it is widely felt, is not sufficiently coördinated, and many decisions of policy remain outstanding. Mr. Walter Elliot, the Minister of Health, on July 13 informed representatives of the hospitals of the Ministry's plan for ensuring coöperation between the medical group officers and the lay sector officers. Dr. J. H. Hebb, director-general of emergency medical services at the Ministry, will meet the medical group officers every Monday, Mr. Neville, the principal assistant secretary in the Ministry responsible for the administrative side of the scheme will meet the lay sector officers every Tuesday, and Sir Girling Ball chairman of the medical group officers, and Sir George Cory, chairman of the lay sector officers will meet Sir George Chrystal, permanent secretary of the Ministry, every Wednesday. At this last meeting Sir Frederick Menzies medical officer of the L.C.C., and Sir Bernard Docker, representative of the London voluntary hospitals, will be present, also Dr. Hebb and Mr. Neville. Immediately after it Sir George Chrystal will report to the Minister on matters of policy, and thus the Minister will himself deal direct with London's special problems. While expressing the view that these arrangements would go a long way towards meeting the immediate situation and should be given a trial, the hospital representatives feared that Mr. Elliot might find it impossible, owing to his other burdens to continue to play the personal part he had indicated.

THE UNNATURAL ATHLETE

ATTEMPTS to introduce more vitality into professional football have become so widespread that the British Medical Association has decided to inquire next autumn into the alleged benefits of using endocrine extracts for this purpose. Hitherto, as Boje remarks,[1] there has been little serious research on the adventitious aids to athletic success. His own paper on the subject ranges over a wide field from cocaine to hormones and from glucose to vitamins. A rough-and-ready classification puts the preparations capable of "doping" athletes in three main categories according to the risk involved. Thus cocaine, Benzedrine (amphetamine), nitroglycerin, digitalis, strophanthin, certain hormones and caffeine in large doses are in Böje's opinion definitely dangerous. At the other end of the scale, ranking as quite harmless, are glucose, oxygen and vitamin B_1. In an intermediate category he would put the cardiac stimulants, Coramine and Cardiazol, ultraviolet irradiation, various salts and small doses of alcohol. Boje admits that there are certain substances which, when given with the skill which comes from a working knowledge of pharmacology, are capable of enhancing athletic activities and achievements. But when he singles out one drug after another for detailed discussion, there is more often that not some catch or "but" which robs the reader of any whole-hearted faith. From the standpoint of sport, this is perhaps all to the good.

MR. E. L. SHERIDAN, F.R.C.S.I., has been nominated, by the Privy Council, chairman of the Dental Board of the United Kingdom in succession to the late Sir Francis Acland. Mr. Sheridan, who is professor of dental surgery in the National University of Ireland, was an original member of the board and has for the past ten years represented qualified dentists practising in Ireland. He is one of the additional members of the General Medical Council appointed by the Privy Council under the Dentists Act, 1921.

NURSING COURSES FOR SCHOOL-GIRLS.—*Last year* the General Nursing Council passed a resolution (*Lancet*, 1938, 1, 807) approving the division of the preliminary state examination into two parts, the first of which might be taken before entering hospital provided that the candidate had followed an approved course of instruction at school. The Board of Education has now issued a circular (No. 1471) explaining the arrangements which they have made in coöperation with the council for courses in anatomy, physiology and hygiene to be given in secondary schools and technical schools for girls who wish to enter the nursing profession. In view of the serious shortage of nurses the board hope that many schools will find it possible to establish pre-nursing courses which they can recommend to the council for approval. *In a report published* some months ago the Interdepartmental Committee on Nursing Services pointed out that the number of probationers required annually was 12,000. This figure is much in excess of the possible supply of entrants from secondary schools. The circular therefore, follows the report in recommending that in addition to courses in secondary schools there should be evening courses in technical schools which can be taken by girls and young women already in employment. There may also be whole-time day courses in technical schools for girls and young women who have left school and are not employed or can afford to leave their employment.

SPECIAL ARTICLES

VENEREAL DISEASE

THE ninth Imperial Social Hygiene Congress met in London last week and on Thursday held discussions of immediate medical importance.

THE SITUATION AND THE REMEDIES

Colonel L. W. HARRISON, presenting a Review of the Position in Respect of Syphilis and Gonorrhœa, said that the number of cases of syphilis (in all stages) dealt with for the first time at the centres in England and Wales (including transfers and those that returned after being struck off the books in previous years) had fallen from 42,800 in 1920 to the provisional figure of 18,034 in 1938, and the number of infections of less than a year's duration (5238 in 1938) had fallen by 42 per cent. since 1931. On the assumption that 40 per cent. of the 42,800 cases dealt with in 1920 were fresh infections (some observers put the figure at 66 per cent.) the decline in fresh cases from 1920 to 1938 could justifiably be taken as about 70 per cent. The infantile mortality from syphilis had risen from 1·34 per 1000 live births in 1912 to the peak figure of 2·03 in 1917; but thereafter, apart from one setback, it had declined steadily to 1·12 in 1922, 0·47 in 1932 and 0·20 (provisional) in 1938. The latter figure represented one-sixth the number in 1912 and one-tenth that in 1917. Further evidence of the decline of syphilis was provided by the results of routine tests in pregnancy: in Battersea the percentage of positive tests fell from 3·5 in 1924 to 0·7 in 1936, in Cardiff the figure declined from 3·1 in 1925–28 to 1·8 in 1935, and in Glasgow the figures were 4·9 and 1·8 in 1925 and 1935 respectively. Between 1931 and 1938 the number of cases of congenital syphilis seen for the first time in treatment centres (excluding transfers and cases registered in any previous year) had declined in all age-groups under fifteen years (in 1938 in the age-group 5–15 years the provisional number of cases, 448, represented a 39 per cent. decline); but over fifteen years, as was to be expected, there was no decrease.

There was thus, said Colonel Harrison, a substantial decline in the incidence of fresh syphilis in England and Wales in spite of defaulting; but could we look forward to a reduction in the incidence of late effects or would a large proportion of defaulters die? He thought that the evidence was against this fear. Firstly, correlating late cases and the amount of treatment received, it was found that in one series of 936 cases (809 with cardiovascular or neural syphilis), of 931 whose history was known, only 8 had had more than an average course of ten injections in the early stages. Secondly, despite the increase of syphilis in England during the late war (87,000 of the total of 102,000, excluding the Navy and demobilisation figures, were estimated to be fresh cases), though the crude annual death-rate from aneurysm per million living had risen in females from 11 per million living in 1922 to the provisional number of 26 in 1938 (the figures for males rose from 45 to 52 in the same period), the corresponding figures for tabes were actually reduced from 7 to 5 in females and from 36 to 24 in males, and for G.P.I. the figures declined in females from 15 to 10 and in males from 77 to 32. Therefore even slight treatment—approximating to one modern course—seemed to have prevented a great amount of aneurysm developing. Nevertheless it was necessary to redouble efforts to get women under treatment in order to reduce the incidence of fresh syphilis and the late effects in future years. Colonel Harrison uttered a warning against blind acceptance of the first positive Wassermann reaction in pregnant women, even when backed by a positive Kahn; although routine testing was valuable in the prevention of congenital syphilis it might be harmful if used as more than a pointer. Secondly, since it appeared that, unlike bismuth, the arsphenamines and mercury failed to reach the fœtus in effective amounts until the latter part of pregnancy, the practice of intensifying arsenical treatment, while excluding bismuth, was probably without effect.

The position as regards gonorrhœa had been favourably affected by the introduction of sulphonamide therapy. But dangers attended failure to use the drugs in optimum concentration, and often practitioners instructed the patient to treat himself, *with unhappy results*. *Action against present ignorance* might take the form of notices sent out by V.D. officers and medical officers, and the British Medical Association might arrange local discussions.

Dr. R. C. L. BATCHELOR (Edinburgh) said that under the Edinburgh venereal-diseases scheme reproduction is advocated both indirectly—for example, by providing attractive premises for the expectant mother—and directly by optimism about the prospect of cure, which was justifiable perhaps with the present remedies for syphilis and gonorrhœa. He thought a hospital-trained sister with special knowledge and experience in venereal diseases was more likely to be successful in social-service work than a male almoner. There was less need of hostels for women and girls now that chemotherapy cleared up infections rapidly, and adequate medical supervision was ensured by admitting girls to hospital for inpatient treatment during the early infectious stages of the disease; furthermore, the struggle for a livelihood could be resumed earlier. Turning to the advisability of continuing routine Wassermann tests in expectant mothers, Dr. Batchelor pointed out that the results of 15,763 blood examinations at the Royal Maternity Hospital and the Elsie Inglis Memorial Maternity Hospital between Nov. 1, 1934, and Oct. 31, 1938, showed the percentage of positive cases to be 0·7 and 3·3 respectively. Although the incidence of syphilis was small, its detection could be of great preventive value to the whole family; its omission would therefore be a retrograde step, especially as in a time of national emergency there would be an increased incidence of syphilis. Dr. Batchelor concluded that a venereologist should concern himself both with the patient and the social implications of his particular case: we were still too easily acquiescent in the degrading and depressing influences that led to venereal disease.

Dr. A. O. FERGUSSON ROSS (Liverpool) suggested instruction in the use of the sulphonamide drugs through postgraduate classes for panel practitioners.

Lieut.-Colonel E. T. BURKE (London) emphasised the necessity of looking into the history and of testing the cerebrospinal fluid, as well as the blood, to detect syphilis in females. The routine test in pregnancy was in his view invaluable, but the possibility of a "false" negative in women who were undoubtedly syphilitic should not be overlooked. In chemotherapy hæmatological examinations were necessary to avoid overdose; but it was equally important to

guard against carriers and relapses due to inadequate dosage, also the test of cure should be more stringent He emphasised that the Wassermann testing of voluntary blood donors was essential, but was not being done

Dr ROBERT FORGAN (Essex) considered that advice regarding chemotherapy would be best offered by medical officers of the Ministry rather than venereal-diseases officers He believed that improved results could be got from a measure of compulsion in treatment

Dr LETITIA FAIRFIELD (London) said that among over 13,000 pregnant women attending London County Council clinics during 1935 the percentage of positive Wassermann and Kahn reactions was only 0 83 (excluding "suspicious" cases), and a similar low figure was obtained in 1936 In 1935 98 per cent of all positive women, 97 2 per cent of those who had four injections or more of arsphenamine, 95 per cent of those who had less than four injections, and 95 per cent of those who had none, went to term Although to these 13 000 women only 3 children as yet known to be syphilitic were born, it was impossible before the lapse of thirty years to prove that the remainder of the children whose mothers gave positive tests were safe Dr Fairfield urged the importance of following up the parents in cases of ophthalmia neonatorum

Dr A MIDDLETON HEWAT (London) contended that there is no agreement among clinicians about the details of chemotherapy and suggested that practitioners should send their patients to clinics for a satisfactory test of cure He favoured separate clinics for cases with vaginal discharge, and said that although he had found no change in hostel attendances among pregnant girls chemotherapy had resulted in a falling off of attendances of nulliparous girls In his experience girls would not go into a hospital bed

Colonel HARRISON said that tissue resistance probably played a part in the lower incidence of syphilis in women The disease was less damaging to a castrated animal under the influence of œstrin than it was to a normal male animal.

Dr BATCHELOR said that in his experience the female nurse almoner brought back over 90 per cent of defaulters The relapse rate of 1102 cases receiving antisyphilitic treatment at the Edinburgh clinic was 0 9 per cent in males (average of 3 6 unit courses) and 3 7 per cent in females (average of 3 unit courses) Of 413 notifications of ophthalmia only 5 per cent proved to be gonococcal Referring to blood donors he recalled that McClusky of Glasgow had reported 2 cases of donors who were incubating syphilis and developed it later, a Wassermann reaction was advisable two months before giving blood, the patient being put on parole in the interim

Mrs C NEVILLE ROLFE, secretary general of the British Social Hygiene Council, in seconding a vote of thanks to the chairman, Sir ARTHUR MACNALTY, remarked that whereas congenital syphilis had decreased as a whole, the problem had not been tackled in such areas as Cornwall and Devonshire

ASCERTAINMENT

At the second discussion, with Prof JAMES YOUNG in the chair, Dr ERNEST PRITCHARD (Liverpool) spoke on the ascertainment of venereal disease in a community Any census, he said must include clinic and hospital cases (the latter being chiefly late ones), cases treated by specialists and general practitioners, and self treated cases, the latter group, owing to the 1917 act, would not present such a problem as it had in the United States Self treatment, however, had increased here since the advent of sulphonamide therapy, and the sale of all drugs of this group should be restricted Methods of assessing the incidence of venereal disease in the U S A included the sending of a questionnaire relating to the number of cases under treatment or observation on a given day, together with a numbered confidential inquiry form, to every person concerned with the treatment of these diseases, the inquiry was repeated if necessary The tabulated figures obtained gave what was called the treatment "prevalence" rate, this in the U S A was 7 7 (syphilis 4 3, gonorrhœa 3 4) per 1000 of population, corresponding to totals of 683,000 and 493,000 cases under observation or treatment for syphilis and gonorrhœa respectively, it was lower in cities of over 100,000 population than in smaller cities The annual incidence of fresh infections with syphilis and gonorrhœa was respectively 4 and 8 per 1000, 71 per cent of patients with syphilis and 51 per cent of cases of gonorrhœa sought treatment in the late stages A second measure was the monthly census From 1929 onwards questionnaires had included the number of cases accepted during one specified month The total number of early cases so obtained, multiplied by twelve, gave the "incidence" of syphilis, often stated as "518,000 fresh infections from syphilis never before treated come to doctors each year" Mass blood testing of different occupational or other groups was also undertaken In the U S A some 2 or 3 million people had been tested, from which the average prevalence of syphilis in the general population was deduced as around 5 per cent, although great variation occurred in different groups, being highest in the coloured race Whereas in 1935 in the U S A the percentage of early cases seeking treatment was estimated at 43 and 57 for syphilis and gonorrhœa respectively, the corresponding figures in Liverpool in the same year were 13 8 and 86 2, syphilis was apparently more prevalent in the U S A, or perhaps cases of gonorrhœa escaped the census

The procedure in Canada followed in general the lines of the American questionnaire and the 1937 census in Toronto was completed in six weeks, 97 3 per cent of the recipients sending in a reply A summary of the results indicated a total incidence of venereal disease of 9 59 (syphilis 5 64, gonorrhœa 3 95) per thousand population The sex incidence of syphilis was 57 per cent males and 43 per cent females Compared with the surveys in 1929 and 1931 early cases of syphilis had decreased by half and late cases had increased by more than half

In the discussion it was maintained that a census is desirable in Great Britain

Mrs NEVILLE ROLFE pointed out that the relative incidence of gonorrhœa and syphilis in the United States Army and Navy is about 8-9 to 1—that is to say, the figures were comparable with those for this country

Dr S M LAIRD (Stoke on Trent) described observations in various parts of Staffordshire in 1937, which showed a percentage of defaulters in early syphilis in the region of 50 per cent, irrespective of age groups, the figure for gonorrhœa being about 30 per cent Contacts outnumbered those treated

Colonel HARRISON considered it hopeless to define the defaulter rate since the standards of complete test of cure and treatment were very variable.

MEDICINE AND THE LAW

Amputation of Leg after Childbirth

THE House of Lords decision in Marshall *v* Lindsey county council in 1937 probably represented the high-water mark of a plaintiff's success against a doctor or a hospital in the matter of puerperal fever Last week the Lord Chief Justice dismissed a much weaker claim in Mitchell *v* Outred and others, without the defendants being called upon to make their reply Mrs Mitchell went into the Crayford (Kent) Russell Stoneham memorial hospital in 1937 for her first confinement Dr T. C. Outred of Northfleet attended her On May 1 a healthy child was born; the child is still doing well According to Mrs Mitchell's counsel, her temperature rose after the childbirth, on May 21, at the wish of her husband, she was removed to her own home; a few days later she complained of a pain in the right thigh which Dr. Outred attributed to neuritis On June 4 Dr. Outred discontinued his attendances as he was going to a practice several miles away. His former partner, Dr. W A. Rogerson, took charge of the patient. Her temperature rose to 104° F; a second opinion was taken; puerperal fever was diagnosed, the patient was admitted to the Miller General Hospital at Greenwich where her leg was amputated on June 24 Mrs Mitchell now claimed damages on the ground of negligence from Dr Outred, the matron of the Crayford hospital, and the president, chairman, general secretary and treasurer of the hospital It will be remembered that in the Marshall case the Lindsey county council provided a maternity home and placed it under the direction of a skilled staff A patient in the home contracted puerperal pyrexia A second patient applied for admission and was admitted without being told of the existing infection The second patient contracted puerperal sepsis and the House of Lords held that the county council was liable Mrs. Mitchell's case was much less definite She alleged that, owing to the negligence with which she was treated by the doctor and the hospital, she developed septicæmia consequent on puerperal fever with the result that her right leg was amputated At the close of her case the Lord Chief Justice ruled that there was no evidence to go to the jury against any of the defendants It had been established that on June 24 it was unhappily necessary to amputate her leg, but there was no evidence to connect the amputation with any negligence or breach of duty on the part of any of the parties whom she was suing. Judgment was therefore given for the defendants with costs Rejecting an application for a stay of execution, Lord Hewart expressed the opinion that the action was entirely misconceived

The experienced counsel who represented Mrs Mitchell could hardly take up the position that the existence of puerperal fever was in itself a proof of professional negligence and a proper ground for the award of damages to a patient. In so far as the particulars of negligence on which the claim was based are to be found in his opening address to the jury, it may be noted that he dwelt on the fact that Dr Outred took no second opinion and made no blood-tests Counsel drew attention to the duty to report the high temperature to the medical officer of health. He described certain entries in the temperature book as danger signals which should have warned the doctor and the nurses of the need of great care The actual temperature chart at the hospital had been destroyed two years ago; counsel said it was obvious that the temperature chart was not kept in the usual way Puerperal fever, he said with full truth, is usually caused by infection from outside, doctors and nurses therefore wear sterilised masks, gloves and clothing while attending a patient and the treatment must be completely antiseptic These precautions were not taken at Mrs Mitchell's confinement (there was evidence subsequently that Dr Outred wore gloves and a rubber apron but not a mask or gown); their absence might well have caused her infection. Counsel observed that Dr Outred administered Prontosil to Mrs Mitchell while she was in the hospital and that apparently this step had the effect of reducing the temperature; afterwards he used the drug intermittently, "in so doing he obscured the signs of puerperal fever which would have warned him if he had seen them" Other complaints, challenged in cross-examination of the plaintiff, were that the hospital was understaffed and that the patient was asked not to ring her bell at night. In concluding his statement to the jury, counsel announced that doctors of eminence would say that the history of the case immediately suggested to them that Mrs Mitchell had suffered from puerperal fever, they could not suggest anything else which would result in the amputation of her leg

The expert witnesses to whom this announcement referred suffered from the disadvantage that their evidence was a matter of surmise at a time long distant from the material events in the case. Dr J. D S Flew, physician to the antenatal department of Queen Charlotte's Hospital, expressed the view that, from the account of the patient's symptoms which he had heard, she must have been suffering from septicæmia when she returned to her home, and that the loss of the leg must have been due to puerperal fever. "How often did you see Mrs Mitchell when she was ill?" inquired the Lord Chief Justice "Never," replied the witness Dr Flew emphasised the importance of the wearing of masks in the labour room and the use of masks and sterile gloves by nurses for the first week after the birth of the child. He was asked in cross-examination whether at Queen Charlotte's there had not been about 5 per cent of cases of puerperal fever among patients in 1937 in spite of every precaution against infection He said he thought the figure sounded rather high Does this not show, he was asked, that, do what you may, you cannot escape the possibility of puerperal fever? The witness agreed. "The occurrence of puerperal fever," continued counsel for the defendants, "does not prove that there has been any fault anywhere?" "I did not say it did," he replied He agreed that many practitioners did not use masks or gowns during a confinement and that the regulations for midwives issued in 1939 do not prescribe that a midwife should wear a mask or gown or gloves at a confinement Dr R. M Fry, assistant director of the research laboratories at Queen Charlotte's, repeated and confirmed previous evidence as to the advisability of gloves, gowns and masks and the need of watching carefully every temperature in the post natal period The loss of Mrs Mitchell's leg, he said, might be due to the thrombus which originated the embolism in the lung, giving rise to a cough from which witnesses had said that she suffered, but the case was an unusual one, he had never seen such a case before "Are you aware," asked Lord Hewart, "of the facts immediately preceding the amputation?" The witness answered in the negative A third expert witness, Mr. Norman White, assistant obstetric surgeon to University College Hospital, gave similar evidence of the need of precautions against

infection and of further investigation when a patient's temperature rose He was asked in cross examination whether the man in charge of the case on the spot, assisted by competent nurses, was not in the best position to judge the proper course The evidence of this witness concluded the plaintiff's case, and, after argument by counsel, the Lord Chief Justice dismissed the action as already stated

Rejuvenation Fraud

If Mrs Mitchell's case failed because she proved effect but not cause and because the claim remained a matter of surmise a plaintiff who had suffered from treatment at a "rejuvenation health clinic" and who had received attention from two "doctors," whose names are apparently not to be found in the Medical Register, won an easy victory in an adjacent court on the same day (Shallard v Arlme and Gustavson) One of the defendants Miss Arlme, carried on the clinic at 14, Herbert Crescent, Knightsbridge, the other, Carl Gustavson, administered the treatment Mrs Shallard based her claim not only upon negligence and breach of contract but also upon fraud The judge found that the two defendants divided the proceeds of a fraudulent scheme for extracting money from a middle aged woman in indifferent health He hoped that other women would profit by the lesson of the plaintiff's disagreeable experience

Mrs Shallard's evidence was that, after nursing her husband for several months until his death at the end of 1937, she was persuaded by Miss Arlme to try the Gustavson treatment at the clinic She was given a pamphlet about his facial and other rejuvenation treatment which was described as absolutely harmless and certain in its efficacy She met Gustavson, who said that he would make her fit and well but that he had never treated anyone who had not first been examined by a Dr Macnab She paid two guineas for this examination and was told by Gustavson that "Dr" Macnab (whom her counsel declared not be a doctor at all) had reported that her condition was good except for the toxins in her body These toxins the Gustavson treatment would remove His fee would be 200 guineas On March 14, 1938, Mrs Shallard entered the clinic She was put to bed and some substance was applied to her face which burned her She was given tablets which made her vomit Next day there was similar treatment Her eyes became painful She was placed in a bath of Epsom salts On March 18 bandages were taken off which tore the skin from her forehead and neck, leaving them sore and bleeding She was in pain until March 28 when she insisted on being driven home Her condition improved by July, in August she had a nervous breakdown, and from September until the spring of this year she was in bad health Two medical practitioners who saw her in October gave evidence of her condition at that date One of them, a dermatologist, said that her face and eyelids were swollen there was some conjunctivitis her skin was thickened and had a mask-like appearance she complained of burning and irritation Her condition he said, was consistent with the experiences of which she complained. The other doctor spoke of having observed acute symptoms of heart failure for which he injected strychnine Asked by the judge how the heart failure could have resulted from the facial treatment, the witness said one cause of it might be worry and fright at the thought of possible blindness and disfigurement

Miss Arlme's defence was a denial that she and Gustavson were partners, though she said that, believing his treatment to be thoroughly satisfactory, she placed rooms in her clinic at his disposal for a consideration of one third of his fees She maintained that, if she had brought Mrs Shallard and Gustavson together, she had done so in good faith, she believed the statements in his brochures, she had not been present at the patient's actual treatment and was not responsible for its results Gustavson did not come into court The judge remarked that he had left Miss Arlme to defend the case alone in a way which belied the manly appearance presented by him in the illustrations to his brochure. Plaintiff's counsel stated that Gustavson, a Swede, had left the country, the Home Office apparently would not allow him to remain At any rate efforts to serve him with a writ were unsuccessful The judge said there was no evidence before him to show whether, at the time when Mrs Shallard received treatment, the clinic in Knightsbridge was licensed by the London County Council, if it was licensed, it was unfortunate that no L C C inspector knew what was going on

Agranulocytosis following Chemotherapy

An inquest was held in Manchester on July 15 on a woman of 36 who died in Manchester Royal Infirmary on the 11th She had been admitted to the Devonshire Hospital, Buxton, on May 26 with rheumatism, she also had chronic catarrh and heart trouble Treatment of the rheumatism progressed favourably, but she developed erysipelas This was treated with sulphanilamide, of which she had 1 5 grammes daily for 16½ days Then the treatment stopped, but it was started again five days later, when she had the same dose for 3½ days On July 7 she complained of a dry throat and a slight swelling of the tonsils was noticed Next day the swelling had increased and on the 9th the patient was transferred to Manchester Mr W F Nicholson, resident surgical officer, said that she was then very ill and it was found that the white cell count was much diminished and that the polymorphonuclear leucocytes amounted to only 2 per cent The diagnosis of agranulocytosis was supported by the results of post mortem examination In answer to the coroner Mr Nicholson said that in reported cases to which he had referred the patients had all taken considerably larger doses of sulphanilamide than were given in the present case He added that the condition was exceedingly rare In recording a verdict of death from misadventure, the coroner said he was satisfied that proper treatment had been given at the Buxton hospital and that the woman was one of the small number of people upon whom the particular remedy had a bad effect

Questions set in the London M B examination

SURGERY

1 Define common acute inflammation, its characteristic symptoms and causes

2 State the various terminations of inflammation, with the treatment of each respectively

3 How do you class wounds arising from external violence? Describe their nature symptoms, and treatment

4 What is the process by which union is accomplished in a simple fracture of a cylindrical bone?

5 Give the different dislocations of the shoulder joint, their symptoms and mode of reduction

6 What is hydrocele—its palliative and radical treatment?

7 Enumerate the different situations and names of hernia with the various conditions in which they may be found

8 Describe the operation for popliteal aneurysm

MEDICAMENTS AND PUBLIC HEALTH

THE British Pharmaceutical Conference was held at Birmingham from July 17 to 20. In his address from the chair, Mr. J. RUTHERFORD HILL said that he was attracted to the subject of medicaments and public health by two events. The first was a monograph by Prof. A. J. Clark dealing with the harm done by proprietary medicines in the production of addiction, accidental poisoning, dangers associated with self-medication, misinformation of the public and financial loss. The problem was summarised in section 22 of the Report of the Select Committee on Proprietary Medicines of 1914 in the words: "For all practical purposes British law is powerless to prevent any person from procuring any drug, or making any mixture, whether potent or without any therapeutic activity whatever (as long as it does not contain a scheduled poison), advertising it in any decent terms as a cure for any disease or ailment, recommending it by bogus testimonials and the invented opinions and facsimile signatures of fictitious physicians, and selling it under any name he chooses, on the payment of a small stamp duty, for any price he can persuade a credulous public to pay." The Select Committee found that the trade in secret remedies constituted a grave and widespread public evil, that the existing law was chaotic and had proved inoperative and that consequently the traffic in secret remedies was practically uncontrolled. The Committee concluded by saying "That this is an intolerable state of things and that new legislation to deal with it, rather than merely the amendment of existing laws, is urgently needed in the public interest." So far the only amendment of that unsatisfactory position is the Venereal Diseases Act (1917), which forbids treatment of these diseases otherwise than by duly qualified medical practitioners and expressly forbids the advertisement or sale of any remedies purporting to cure these diseases.

Prof. Clark concluded his monograph by saying: "The health interests involved in the sale of medicines are vastly more important than the million pounds which the Government obtains from the taxation of proprietary remedies. The clearest line for the Government to take would be to say that it did not wish to tax any remedy that was beneficial to the health of the people and wished to suppress all those that were useless and harmful. This would imply the abolition of the Medicine Stamp Duty." The second event was the debate in the House of Lords in July last year, when Lord Horder moved for papers in view of the enormous growth in the quack medicine trade and the incongruity of exercising no control over the deleterious effects of such trade upon health at a time when serious effort is being made to improve national fitness. He rightly describes the advertisements of many of these "proprietary medicines" as "grossly misleading and fraudulent." He pointed out that in continental countries, and in the United States of America, exploitation of the people by means of proprietary medicines was forbidden, while in our own Dominions of Australia and Canada offenders were liable to heavy penalties for making false or fraudulent claims. It was humiliating to think that Great Britain remained complacent in face of this growing menace to the health of her people.

The problem has at the moment been brought prominently to the front by the recent intimation by the Chancellor of the Exchequer that he had decided to abolish the Medicine Stamp Duties in this year's Budget. In a recent High Court case the judge described the Medicine Stamp Acts and relative regulations as a mass of confused and obsolete verbiage that should be swept away. The Chancellor seems to have accepted this view and remains of the same opinion. That has long been my opinion, and it is an opinion widely held among pharmacists who have had experience of the Acts. In reality medicines required by sick people are not a proper subject for taxation. The Medicine Stamp Act is perhaps the only remaining example of an unsatisfactory kind of legislation in the time of George III, when the British Exchequer was seriously impoverished by the Napoleonic Wars and the American War of Independence. All other petty, vexatious and restrictive taxes were abolished under the fiscal reforms of W. E. Gladstone; but the Medicine Stamp Act, being a small affair, has been allowed to remain. It is an anachronism and should be abolished. But it has, however, operated as a restraining influence, through its ad valorem stamp duty and the reservation of the right of pharmacists to sell known and approved remedies; to abolish suddenly all restraints might be prejudicial to the public-health interests of the community, and widen the gap alluded to by Lord Horder. By a piece of skilful parliamentary tactics the council of the society and the allied interests are to be congratulated on persuading the Chancellor to continue the Medicine Stamp Duties for another year, but it will be well to keep in view the total abolition of Medicine Stamp Duty when the public-health aspect has been adequately secured. I now come to my constructive proposals.

THE RECOGNITION OF MEDICAMENTS

There is need for some central authority to recognise proper and reliable medicaments. A combination of the British Pharmacopœia and the United States Pharmacopœia might be the first stage in securing a Universal Pharmacopœia, and Dr. C. H. Hampshire has been called upon to frame such a world pharmacopœia. But this does not solve the whole difficulty in settling what are proper and reliable medicaments. New drugs and methods of treatment are constantly being introduced. It is necessary, therefore, to have some standing authority with power to act and make recognitions and regulations as occasion arises. I have in mind some such body as the Council on Pharmacy and Chemistry of the American Medical Association which publishes an approved list of new and non-official remedies, the purpose of which is to protect the medical profession and the public against fraud, undesirable secrecy and objectionable advertising in connexion with proprietary medicinal articles. To be effective any such representative body would need to have parliamentary sanction.

THE DEFINITION AND CONTROLLED SUPPLY OF MEDICAMENTS

The welter of names and the puzzling and confused nomenclature of medicaments calls loudly for some simplification and clarification. Some action seems necessary so that we should not have the same definite chemical substances put on the market by several manufacturers under different proprietary names. There should be some limit also to the putting up of mixtures of known substances under a proprietary name, so that the pharmacy shelves shall not be loaded with several proprietary preparations which are really combinations of well-known medicaments.

In a well-regulated state effective arrangements should be made for some reasonable control in the

supply of medicaments Such control must be solely in the public interest and never for the benefit of a particular class The principle is already in operation on a limited scale About 90 years ago there was widespread public alarm at the numerous cases of poisoning by arsenic which was sold indiscriminately by anyone The Arsenic Act of 1851 was passed by which it was attempted to secure public safety by imposing regulations About 10 years later public alarm was again created by a series of poisoning cases After a prolonged inquiry Parliament was persuaded that mere regulation was ineffective, and that the real protection of the public could only be secured by providing that poisonous substances should only be distributed to the public by the hands of a duly qualified pharmacist This principle that the safety of the public is secured by limiting the distribution of such substances to properly trained and qualified persons is the basis of the Pharmacy Act, 1868 This principle is confirmed and extended under the Pharmacy and Poisons Act, 1933

A WIDER APPLICATION OF PUBLIC CONTROL

I suggest that there is a strong case for a much wider application of such public control It would be in the interest of the community as a whole that the dispensing and distribution of all medicaments should be entrusted by the state to those persons who have complied with the statutory requirements as dispensers The mere fact that an article can only be obtained from a properly qualified person suggests to the purchaser caution in the use of the article, and the pharmacist would naturally, as he does in the case of powerful drugs, give any necessary guidance or information The qualified pharmacist, though he knows little or nothing of pathology and would not presume to diagnose or prescribe, knows enough about the evidences of illnesses to be able to warn a purchaser in cases where the article he wants to purchase is distinctly contra indicated The matter is one requiring most thorough investigation and it is suggested that the Government should be approached by joint representatives from the medical and pharmaceutical professions requesting the appointment of a Royal Commission to investigate and report as a basis for legislation

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

THE ATTACK ON CANCER

THE Department of Health for Scotland has issued a circular on the application of the Cancer Act, 1939, to Scotland As is now well known, the act places on local authorities the obligation to make suitable arrangements for the treatment of persons who are suffering from the disease The arrangements proposed are to be submitted to the department by the end of next March, and before submitting them the authorities must consult with the governing bodies and medical and surgical staffs of voluntary hospitals providing services for the benefit of their areas and with representatives of the local practitioners To avoid unnecessary expense and overlapping it is recommended that arrangements should be made for regional schemes In this way the less populous districts, particularly in the Highlands, will be able to obtain satisfactory services that they might not otherwise be able to afford No very large provision of new hospital beds by councils is anticipated by the department, particularly in those areas which are already served by large voluntary hospitals Here it is thought that local authorities will wish to coöperate with the voluntary hospitals in helping to develop existing facilities, by contributions towards the capital cost, both in accommodation and equipment In addition, payments will be made for the maintenance and treatment of patients Further, councils are to include in their schemes arrangements for follow-up, supervision of patients between visits to treatment centres, record keeping and the travelling expenses of patients However, they are to recover from patients such proportion of the cost as can reasonably be afforded

By instruction of the public it is hoped to convince cancer sufferers that early treatment holds considerable chance of cure and to overcome the dread that so often leads to dangerous delay

REVASCULARISATION OF THE HEART

In a lecture lately given in Edinburgh Mr L F O'Shaughnessy, of London, said he was satisfied that artificial adhesion between the omentum and the heart is compatible with normal function, and that the heart can be vascularised through the junction He employs omental grafting in preference to the pectoral muscle method of Beck, and he supplements the graft by the application of aleuronat paste to promote the formation of adhesions In a few instances he has carried out cardiopneumonopexy as an alternative

Surgical treatment of patients suffering from cardiac ischæmia should, in Mr O'Shaughnessy's opinion, be undertaken only when the outlook under medical treatment is uncertain A suitable patient might, for example, be a man in middle life who has had one attack of coronary thrombosis and has made a poor natural recovery If pain and cardiac dysfunction still remain six months after the accident, vascularising operations may be employed to supplement natural recovery Patients with disease round the coronary orifices but healthy coronary trees are suitable for operation both theoretically and practically In the case of angina pectoris of effort, in which the degree of coronary artery disease may be hard to estimate, the uncertain prognosis without grafting must be balanced against the risk of the operation, and the patient must make the final decision It is probably undesirable to operate on patients over 65 years of age or on those with gross renal or cerebral arteriosclerosis Moderate respiratory affection is not a contra indication, since with modern anæsthetic methods and with the new and simpler extrapleural approach to the pericardium postoperative respiratory complications are uncommon

Mr O Shaughnessy gave details of some of his failures as well as some of his successes In one series of 20 cases of cardiac revascularisation 15 patients had angina Of these, 5 died on the table, 1 died from uræmia three months later, and 1 died from heart failure two months after operation Of the survivors bedridden patients were able to become active and some were able to return to work. This ability to return to a normal life is to be considered the criterion of success

THE LATE PROF JOLLY

Scottish medical men will have learnt with regret of the death in Cape Town of Dr W A Jolly, professor of physiology in that university Prof Jolly was an Edinburgh man and an Edinburgh graduate, and he worked in the physiology department in

Edinburgh before going to Cape Town in 1911. Among his many contributions to physiological knowledge will be recalled especially those concerned with electrophysiology, internal secretions, and cerebral function. In collaboration with W T Ritchie he published the first electrocardiograms of human auricular flutter, and gave the name to the condition. His alma mater conferred on him the honorary degree of LL D in 1926.

VIENNA

(FROM OUR OWN CORRESPONDENT)

MORE NON-ARYAN PRACTITIONERS TO PRACTISE

As was mentioned some months ago (*Lancet*, Nov 19, 1938, p 1191) most persons of Jewish nationality practising in the Austrian countries have lost their right to practise, except a limited number required for the remaining Jewish population. Lately however it has been found necessary to admit another batch of practitioners of this kind, since most of those admitted in October, 1938, have been forced to emigrate Now again we are informed that a number of former general practitioners have been allowed to renew their professional activities. They are mostly men well above 60 years of age, for nearly all the younger ones are now out of the country trying to find a living somehow somewhere. While last year only those doctors who had seen active service in the world war were eligible for consideration, now hardly any differentiation is taking place. Even a number of female practitioners, including younger ones, have been allowed to practise. In the only Jewish hospital there is a constant fluctuation among the chiefs of departments Nearly all the prominent men, also numerous trained assistants and nurses, have left the country already, so that those now in office are overworked and the quality is not what it was a year ago. As a result of the constant emigration, the bulk of the Jewish population of Vienna—about 100,000 persons now, 50 per cent of what it used to be—are elderly people aged between 50 and 100 Children and young adults are rarely seen nowadays, and old and ailing paupers are all that is left for the newly admitted doctors to make a living from.

SHORTENING OF THE MEDICAL CURRICULUM

Some time ago the Minister of Education announced that, owing to difficulties of procuring the necessary number of young persons for the various academic professions, the medical curriculum would be altered, beginning with the new summer term of April, 1939. The duration of medical studies is to be shortened by about two years. The practical training of one year, which hitherto had to be taken after completing the curriculum of 11 semesters or 5½ years, will be now compressed into the studies, which will now last only 10 semesters or 5 years. The examinations, which hitherto took one extra term of 6 months, will also be interpolated "into the time taken up for studies, so that the students will gain two full years, in comparison with the requirements in force up till now" The new curriculum requires the student to take up a number of new studies hitherto unnecessary,—e g, "racial knowledge," problems of population, and practical pharmaceutic botany. Furthermore, the student must take part for 6 weeks in agricultural or factory work, study radiological therapy, "natural therapeutics," occupational diseases, child welfare, accident and first-aid surgery, and industrial hygiene. The Minister expresses his expectation that the shortening of the curriculum and the increase in subjects to be studied will "induce the students to concentrate their efforts to reach the desired aim to the advantage of the national welfare" It remains to be seen whether 5 years' study is sufficient to maintain the high standard of the German medical practitioner, as recognised hitherto

THE NEW "WIENER MEDIZINISCHE GESELLSCHAFT"

In the train of the new regime in Austria, the famous old "Gesellschaft der Aerzte" has been dissolved—after having celebrated its centenary in 1937. The greatest medical names of Germany—including a vast number of Jews—were among its members. Now in its stead a new "Wiener medizinische Gesellschaft" has been formed, designed to serve the needs of practitioners as well as scientific research, and only "Aryans" are admitted Sections of this new society will take the place of all the former specialist groups, and among the new sections is one for military medicine. The president is a politician, who is also a doctor—the district governor of Vienna—and prominent representatives of the various specialties may be entrusted with the task of giving their opinion regarding any question of the nation's health A lecture and demonstrations will be given at every meeting of the society. At the opening session the president, and also Professor Hamburger, explained that "the new principles adopted in the politics will also be governing the evolution of medical science in national-socialistic Germany." Freedom from preconception must be done away with, and a renascence of medical science based on national-socialistic ideology must take place.

RESTRICTIONS IN PRESCRIBING NARCOTICS

With the new year 1939, the pharmacopœia of the German Reich was introduced in Austria and with it the regulations about the prescribing of narcotic drugs. Every prescription of these drugs must show, besides the quantity, the name and address in full of the prescriber, the date, a specification of the application and use of the remedy, the full name and address of the patient, and the remark, "prescription entered or registered" The physician must keep a special book, in which he enters a full copy, with date, address and name of patient, of every prescription containing one or any of these narcotic drugs. He must keep a separate book for cocaine and another for morphine, and show it to the controlling officer of health if required. It is very interesting that these regulations do not apply to dionin, codeine and peronine and substitutes for cocaine In parentheses, it should be stated that one narcotic drug must not be prescribed in combination with another narcotic drug, and that a 1 per cent. cocaine solution intended for use elsewhere than on the eye must be mixed with 1 per cent. atropine sulphate solution.

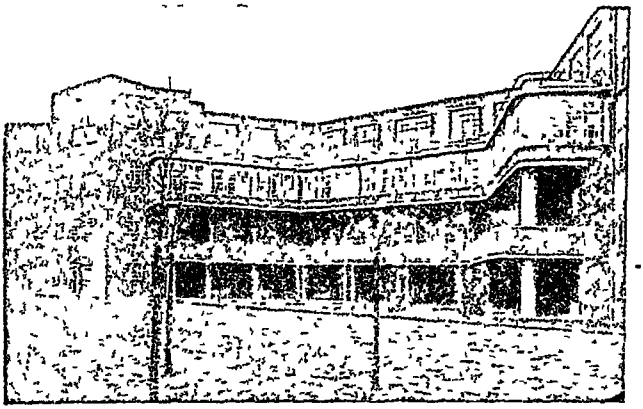
INDEX TO "THE LANCET," VOL I, 1939

THE Index and Title-page to Vol. I, 1939, which was completed with the issue of June 24, is now in preparation A copy will be sent gratis to subscribers on receipt of a postcard addressed to the Manager of THE LANCET, 7, Adam Street, Adelphi, W C 2 Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

THE MAUDSLEY HOSPITAL

OPENING OF PRIVATE BLOCK AND CHILDREN'S WING

ON July 14 the Earl of Athlone, in opening the new private patients' block and children's department at the Maudsley Hospital Denmark Hill, said that his presence, as Chancellor of the University of London, marked another tie between the University and the London County Council Thirty-one years ago Dr Henry Maudsley gave the Council £30,000 to aid in building a hospital for mental illness, in which early, curable cases were to be treated, exact research was to be promoted and medical teaching in psychiatry was to be provided The present building, which had cost the Council, to date, some £236,000, was the outcome of Dr Maudsley's gift It marked the completion of the last section of a large scheme of structural improvement which has been going on for six years



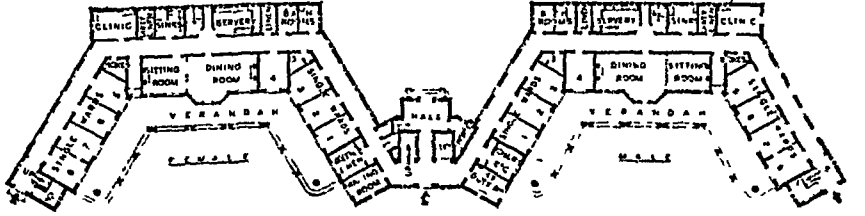
Private patients' block *City General Advertising Service*

DESCRIPTION OF EXTENSION

The small provision originally made at the Maudsley for treatment of private patients in single rooms was some time ago appropriated for other purposes, and the need for adequate private accommodation has become acute The new private block—a building of two wings, fronting De Crespigny Park—is designed to meet the needs of persons who desire treatment, but do not find it congenial in open wards, and are prepared to pay a charge which will cover the cost of separate accommodation and care in single rooms There are three floors, each taking patients of either sex. The structure and organisation are such that very careful classification will be possible, and no patient will have to be treated with others whose illness is of a different and possibly disturbing type No patient will be admitted who does not come in voluntarily Patients will not be received unless the outlook for recovery is good, there is no intention of receiving chronic patients or retaining those whose conduct would be likely to disturb others The new building does not communicate with the original hospital buildings except by a subway and lifts, it encloses one side of an attractive garden, for the use of the private patients, on the other sides are the new children's block, the nurses' home, and buildings which were part of the first extension of the Maudsley, in which are rooms for occupational therapy and physical treatment, an operating theatre, a gymnasium, an entertainment hall, a billiard room, and a library There is an attractive roof garden in the Italian style for those needing greater privacy than the downstairs garden will provide The new building has a wing shaped plan and gives most of the rooms a southern aspect, and there are open verandahs on the ground floor, open balconies on the first floor, and glazed solaria on the second floor

The new children's block has been planned to meet the complete lack of adequate inpatient facilities for child psychiatry in Great Britain, and to provide separate accommodation for an outpatient clinic for children It is intended, not for the backward or mentally defective child, but for the nervous and difficult child who needs individual attention The outpatients' part of the new building is already fully at work, the residential accommodation is not yet occupied Here also the roof space (part of which is enclosed) has been used as an additional playground The block contains, in addition to the wards, consulting and other medical service rooms, a mothers' waiting room, a play room and a room for social workers

In the external treatment of all the new buildings multi coloured facing bricks have been used, to ensure harmony with the existing hospital building The entrances to the buildings have been used as focal points for the design, and, in the children's block, have been adorned with sculpture by Miss Juliana Allan, A R B S, who has also executed the two small figures to be seen in the roof garden The cost of the present and previous extensions has been about £174,000 The main contractor for building work was W H Gaze of Kingston on Thames Mr E P Wheeler, until recently architect to the Council, was responsible for the design



GRAINS AND SCRUPLES

Under this heading appear week by week the unfettered thoughts of doctors in various occupations. Each contributor is responsible for the section for a month; his name can be seen later in the half-yearly index

FROM A WOMAN PUBLIC-HEALTH OFFICER

IV

THIS week has brought from the far corners of the Empire friends old and new with good tidings of an increased interest in communal health and of many fine beginnings in preventive and hospital projects But I do not wish to mitigate the picture I drew last week of the serious arrears to be overtaken in Colonial hygiene and the need for a *continuous* public effort at home and abroad There is always a danger that "long-term planning" may be left suspended in mid-air for lack of funds if a call arises for expenditure in another direction—and all health campaigns worthy of the name must be planned and financed for years ahead Not without reason one fears that Defence may be the enemy of Health unless the importance of the latter is fully appreciated

* * *

One has tried hard to keep A R.P out of these notes, but it gets under the skin with its constant reminders of the war years. All of us have, I suppose, our private list of the Minor Horrors of War which irritated most Mine included the depressing darkness of the streets . . . the shortage of small essentials like paper and wood . . the nagging difficulty of getting small repairs carried out . . and the curious way in which people were changed. Courteous and friendly shop-assistants and bus-conductors (whom I usually find as wonderful as visiting film-stars find our policemen) become insolent and unhelpful We have all to be under Authority in war-time and one found that power descending on unaccustomed shoulders brought out unexpected dignity and competence in some but also gave the bully and sadist chances they never get in time of peace

One minor nuisance, which at times assumed major importance, is worth recounting as it is more amenable than most of the above to prophylactic measures I refer to the habit of untruthfulness and slandering which becomes epidemic during hostilities The Russians in England and the Angels at Mons were harmless enough, but the War Babies legends were not so good for national prestige, and the reckless slanders on cabinet-ministers and on anyone high or low with German connexions were very bad indeed Indescribable unhappiness was caused and several innocent persons who had made great sacrifices for their country were driven to suicide Looking back one wonders whether the hate engendered by officially tolerated—or even fostered—atrocity stories may not have played some indirect part in producing the present unhappy situation It did no-one any good to gloat over the notion of women with breasts hacked off or babies with hands cut off at the wrist By an odd chance I was able to investigate several of these legends The women with amputated breasts turned out to be a couple of ordinary cases of carcinoma mammæ seen by visitors to a ward where there were also Belgian refugee patients One alleged victim of the Bolsheviks was a Polish refugee baby who, as his father anxiously explained, had (*a*) never seen a Bolshevik, and (*b*) been born like that! Another Belgian baby without a hand and forearm also turned out to be a case of congenital deformity Not a single authenticated case of deliberate mutilation was ever traced, but certain newspapers went on repeating the stories till the end of the war. The Scots had a better way. Quite early in the war an old law against "leasing"—i e, spreading lies to the public detriment—was revived and at least two people (one a town councillor) were prosecuted under it, to the great benefit of public morale In England it is possible that the law against "creating a public mischief" might be utilised to the same useful purpose, if occasion again arose

* * *

The war recollections most vivid just now are those associated with the evacuation of children More power to the elbows of those engaged on this good work; but I think there is a tendency to exaggerate the effect of the whole business on the nervous system of the child The Spanish experience confirms the impression formed by many of us who were in bombed areas in the last war, that children suffer much less than adults from alarm during raids. Their attitude is largely determined by that of the adults who have charge of them One noted this in the first war refugees one saw—i e, the horde of Belgians and French who poured into Calais before the rapid German advance at the end of October, 1914 I helped to feed the refugees in the canteens there and it was remarkable how quickly they regained normal calm and cheerfulness after a meal and a sleep Later, in the East End of London the frequent raids put children under considerable strain but they stood up to it uncommonly well

The morning of the first daylight raid (in June, 1917) found me examining children in a special school for mental defectives (From that simple statement you may gauge the difference in the calls on the medical profession then and now) The little M.D.'s were certainly a bit pale and jumpy but their sleep had been badly disturbed by almost nightly vigils in the overcrowded Underground stations which were then the only refuges. "Being dragged about like a sack o' pertaters" as one little boy indignantly described it Suddenly the air-raid warning sounded and a little later came the bursting of shells. The children's attention began to wander even from the absorbing tests of Messrs Binet and Simon "Wa, it the 'Uns?" It was . At 11 50 a terrific bang shook the school and the children ran whimpering from their class-rooms into the hall. A tiresome little girl began to relate horrific anecdotes derived from a brother home on leave, and it was some minutes before the head-teacher could persuade them that the wicked "Tobes" (Taubes) were on their way home by now. "But how am I to get the children home" whispered the head; "they'll want their dinners and heaven knows when the all-clear will come" This would never do, so I slipped out through the deserted streets and bought an armful of buns On the way out I called in at the school for physically defective children downstairs to see how the many cardiac cases (some very severe) were bearing up. "Very well, thank you!" The teachers had started community singing and an elderly attendant serving lunch had broken into song with a highly successful comic effect At about 12 30 the all-clear sounded, the M D children cheerfully scampered off home with mouths full of bun. Then I realised how near

we had been to tragedy In a neighbouring school a bomb had passed through the boys' department and killed 2 boys, through a girls' class room and killed a girl, and then exploded in the babies' room and killed 15 Round the school gates stood a crowd of stricken people, mostly women with a few young men in khaki and elderly civilians They neither moved nor spoke, but just waited patiently to know the extent of the calamity Firemen from the docks were clearing the bodies from the wrecked infants' department and already a row of queer little dirty bundles lay under the playground shed In the doorway I met one of the firemen with some thing in his arms a thing like a charred rag doll with one torn limb protruding to show what it had been Tears were pouring down his blackened face and the policeman who had the bundle in the shed beside the others was weeping too Later we learnt that very few if any children had been merely injured There had been no panic anywhere in the building Incredible as it may seem the five year old children in the next room to the fatal babies' room did not leave their seats when the bomb burst The teacher made them fold their hands and say a prayer and their confidence never wavered. Moreover 50 stalwart infants presented themselves at 2 o'clock for afternoon school and were very disappointed that business was not as usual One of the teachers suffered for a time from nervous shock but none of the children had any untoward after effects that we ever heard of

The next air raid was mercifully less tragic I had somehow been inveigled into judging at one of those detestable functions, a baby show The raid took place half an hour before the show was due to begin, but hardly an entrant failed to appear and no mother mentioned the raid

It was good to see from these and other episodes of what finely tempered metal the outwardly soft Londoner is forged Perhaps that is the true purpose of nationalism—to make one realise of what great things people of one's own stock are capable, and to put heart into one's efforts to overcome imperfections

* * *

Later I was privileged to serve with two of the women's uniformed services and a new world opened up The medical supervision of women living in camps and in aerodromes, the inspection of quarters, the technique of medical boarding and many administrative problems effectively stopped one from worrying who was going to win the war In addition one had to wrestle with the Treasury, as St Paul fought the wild beasts at Ephesus, to get reasonable treatment for oneself and one's staff I was blessed above any woman's deserts in the chiefs and colleagues (male and female) which a kind fate provided both in the Q M A A C and the R A F, and only one unsatisfied query remains from those crowded years Why does the spectacle of a woman in uniform arouse such hostility in the breasts of many otherwise admirable human beings? Common sense might suggest that the replacement of men of fighting capacity is of urgent importance in wartime or the heads of combatant services and the Treasury would not sanction the scheme, that it is impossible to employ women in close association with men in camps and barracks without putting them into some sort of uniform, that they must be under some sort of formal discipline, and finally that any persons—men, women, or children—who have to be moved about in groups must be drilled and taught to march It is all as simple and inevitable as that! Yet even the bland announcer of the B B C in describing the Hyde Park review interrupted his paean of praise to drop some childish and "catty" comments on the new Women's Auxiliary Territorial Service—whose members by the by make considerably more sacrifices than the women in more fashionable services We shall indeed be foolish if we attempt to create rivalries or discords in the symphony of essential national service

PARLIAMENTARY INTELLIGENCE

ON THE FLOOR OF THE HOUSE

By Medicus, M P

Another week of Peace passes by. Twelve thousand naval reservists are called up for July 31, thirty thousand militia begin their six months training British forces, including British aeroplanes, take part in the celebration of the French Revolution on July 14 in Paris Britain and France agree to give Poland some eight and a half millions to help her maintain her army on a mobilisation footing The Soviet Mongol army defeats the Japanese-Manchukuo army Negotiations begin in Tokyo about Tientsin outrages on British subjects General Franco says Spain will remain neutral in a future war unless her vital interests are affected Hong-Kong brings in conscription for British subjects A Japanese crowd try to break down gates of British embassy in Tokyo Foreigners are expelled from the Tyrol And so on

In these circumstances the ordinary threat and counter threat of the parliamentary battle changes its character For this Parliament of Great Britain knows how to coöperate as Mr Lees Smith observed in the short discussion on the Members' Fund Bill, when the occasion demands

Civil Defence has now rambled through its last phases—on the existing bill at least—and the Lords' amendments have been considered How satisfactory or unsatisfactory medical arrangements are to be will be found out by experience But the bill does not so much lay down details of organisation as give powers and powers of a very sweeping character And on the medical side they are powers which ought to be used to the full at once The powers conferred on the Minister and on the local authorities are enough to make a good organisation and a workable organisation possible, but it will only be done by a general all round coöperation of all concerned and with not too much red tape about it

* * *

On Friday last, after a discussion on overseas trade, the final stages of the Milk (No 2) Bill were taken and the Minister announced that now there really would be milk available for expectant and nursing mothers and children under five and there was now no limit of money The scheme last year —promised then with equal confidence by the then Minister—did not bring about the supply of milk for the mothers and young children because of the Ministry's failure to get agreement as to distribution. This time the Minister promised that the distribution should not be held up The Milk Marketing Board agreed and he hoped and expected the distributors would agree too But if they do not then other

means of distribution will have to be found, although this was not stated in the debate. What was stated however by Sir Reginald Dorman-Smith, third Minister of Agriculture in the reign of Prime Minister Chamberlain, was that the Government could make no estimate of how long it would be before their methods would result in clearing out bovine tuberculosis and guaranteeing milk against other infections. On which it was proposed by the Opposition that the Government should introduce a one-clause bill giving power to local authorities to institute pasteurisation whenever or wherever the condition of the milk required it.

During this debate there were sometimes less than 40 members in the Chamber, so that the debate could at any time have been held up by the call for a "count" so as to bring it up to this minimum 40 which is the quorum But it was not lack of interest in milk or in public health which caused this. For on one day of the Finance Bill debate there was an actual count A day too on which Sir John Simon made a statement that the amount required for defence must be increased by 170 million pounds Despite the fact that these defence preparations make such a military rattle as to drown the sound of ordinary debate a good deal of ordinary parliamentary business is going on all the time.

* * *

The health and housing committee of the Conservative Party met to consider the next step with regard to the medicine stamp duties The fact that the Chancellor of the Exchequer was forced to abandon his attempt to repeal these duties this year by the consensus of opinion in the House lays a heavy responsibility on those who opposed this course. This Conservative committee, whose chairman is Sir Francis Fremantle and whose secretary is Captain G. S. Elliston, decided to ask the Chancellor and the Minister of Health jointly to receive a deputation who would submit suggestions for a revision of the stamp duties and for legislation to secure control of proprietary and other remedies in the interest of public health The Government is also making moves in the same direction and the Labour Party have their own suggestions. It is to be hoped therefore that before the next budget a scheme will have been generally agreed upon. The scheme should, as the select committee proposed, be one to control not only medicines but also quasi-foods, quasi-beverages and instrumental appliances of one kind or another.

If Peace breaks out, we shall get a good many things done and, if not, DORA may be even more expeditious

FROM THE PRESS GALLERY

Milk Bill

WHEN the Milk Industry (No. 2) Bill was considered in Committee in the House of Commons on July 12,

Dr. EDITH SUMMERSKILL said that the most undesirable feature of the bill was that the taxpayer was being asked to subsidise accredited and standard milk which was neither clean nor pure nor safe. Not one penny should be given to producers of this kind of milk. Forty per cent. of cows had tuberculosis, and it was these cows that were producing accredited and standard milk. Every year 2000 children died as the result of infection from milk which was called standard and accredited. Three-quarters of the cases of St. Vitus' dance, and three-fifths of the cases of infected bone in children were due to infected milk Yet the Minister had the temerity to say that he intended to subsidise this milk, which was a danger to the community. Nobody should profit by producing such milk, and the Minister should reconsider the schedule.

The schedule was agreed to, and the Committee stage concluded.

CHEAP MILK FOR LOCAL AUTHORITIES

The bill came up for third reading on July 14, when the Minister of Agriculture indicated the provisions of the cheap milk scheme, and said the Milk Marketing Board was ready to submit a scheme to him at an early date.

The Government had reviewed the question of the loss likely to be incurred by the board in such a scheme, and had decided to make an Exchequer grant available for the period to the end of September, 1940, at a rate sufficient to ensure the board a return of 1*s.* 2*d.* a gallon on the average over the year. This figure had been reached on the basis of the experience of the Special Areas schemes The rate would be reviewed in the light and experience gained during the year. The main features of the new scheme would be on the lines of the scheme in Scotland Milk would be made available to local authorities for maternity and child welfare schemes at a reduced rate of 2*d.* a pint. The distributive allowance would not be more than 8*d.* a gallon. Local authorities would be able to authorise free milk, or milk at part payment on the full payment of 2*d.* a pint. The balance of the cost of milk supplied at less than 2*d.* would, as at present, fall on the local authority's funds. The Exchequer contribution was to enable them to sell at 2*d.* a pint. Each authority which wished to participate would prepare its proposals and submit them to the Minister of Health, who would coordinate them. There would be no limit to the amount of grant that could be made by the Treasury. The only limit would be the amount of milk they could get down the throats of mothers and children.—Dr. HADEN GUEST said that, as a convinced advocate of the value of milk, he had always been held back by the thought that milk was not an absolutely safe fluid for children to drink. Every doctor would be an enthusiastic supporter of a "drink more milk" campaign if the Minister introduced a bill for pasteurisation.—The bill was read the third time.

Docking and Nicking of Horses

In the House of Commons on July 12, Sir R. GLYN asked leave to introduce the Docking and Nicking (Prohibition) Bill, to prevent the docking and nicking of horses and the importation of docked and nicked horses. He said that a similar bill passed through all its stages in the House of Lords last session and certain amendments were inserted which the promoters of the present bill proposed to adopt. Under the existing law the operation of docking was illegal, unless performed by a veterinary surgeon, and the animal must at the time be completely anæsthetised But the horse was undoubtedly subjected to torture, as a result of the operation which was unnecessary. The only excuse for docking, other than fashion, was that it took more time to keep the animal clean if it was not docked. That was giving way to laziness If a horse's tail was docked and it was stung by flies the animal's nervous system was broken down and in time it became ill-tempered. Every country in Europe had now adopted a similar scheme Under clause 2 of the bill, it was provided that a certificate of a veterinary surgeon should be obtained if the health of a horse's tail was affected. In other words, docking in future would be part and parcel of veterinary science for health reasons alone. It was provided that the act should come into operation on Jan 1, 1940. In March at a conference of the veterinary services of Europe at Munich it was unanimously agreed that docking should be made illegal and, owing to the rapidity of totalitarian law-making, Germany had already passed a law to the effect.

Leave was granted and the bill was brought in and read a first time.

Malnutrition

In the House of Lords on July 12, the BISHOP OF WINCHESTER called attention to malnutrition and asked H M Government if they proposed to take further steps to provide milk either at a reduced price or free to expectant and nursing mothers, children below school age, and children now at school The figure of 92 per cent admitted as fit to the Militia might suggest there was really no serious malnutrition in the country But there was a somewhat startling contrast between these figures and the figures for entrance to the other armed forces Not long ago 60 per cent of applicants for the Army were rejected on physical grounds, and 35 per cent of applicants for the Air Force had been rejected Was this a result of the fitness campaign, or a change of standards?

The effect of malnutrition on infant mortality was shown in the following figures In the well-to-do classes it was 30 infants per 1000 population, in the working classes 70, and among the unemployed 100 per 1000 Maternal mortality was closely connected with nutrition In 1934 the rate in Wales was very serious, and reached in part of South Wales over 11 per 1000 Then free meals were given at the clinics, and the next year the rate had fallen to a little over 4 per 1000 The one difference apparently was that in the earlier year they had insufficient food, and in the next year had sufficient food

The causes of malnutrition were two—partly ignorance, but much more largely low wages There was a strong case for a policy of family allowances, but there were serious difficulties, including the opposition of the Labour Party and the trade unions

A more direct way of dealing with malnutrition was by further provision for cheap and free milk. It was deplorable that the money set aside under the Milk Act last year for providing milk to expectant and nursing mothers and children under school age had not been used He hoped the Government would make it plain on whom the blame rested A large amount of milk went into the factories every week, at a much lower price than it cost to supply school-children with milk We were not in the position of another country where the choice had to be between guns or butter He was asking for guns, butter and milk The health of the people was as necessary for national defence as the armaments that might have to be used

Lord SNELL said that to feed hungry children was not only right in itself but was a good national investment The child was the child not only of John Smith, but of John Bull The trade union difficulties in regard to family allowances were serious ones, that some inquiry should be made to allay their fears

Lord HANKEY said that as Secretary to the Committee of Imperial Defence he was profoundly shocked and humiliated by the fact that year after year more than 50 per cent of the men offering for enlistment in the Army were rejected for physical and medical reasons The late Sir Walter Morley Fletcher, then secretary to the Medical Research Council, assured him that the defects which caused these rejections were curable by proper nutrition, but that it took at least 15 years to translate research into action in such matters Because of the satisfactory results in enlistment for the Militia they must not desist THE LANCET pointed out that there was no specified minimum of height, weight or chest measurement for the Militia, and that some of the men with minor defects of feet and vision who were placed grade 2 (a) of the Militia, would be rejected for the Regular Army, and that even for the Regular Army the standard was lowered in 1936, and since 1937 recruits had not been rejected on dental grounds

The last report of the Medical Research Council stated —

"Only by improving the general health and eliminating disease can it be hoped to reduce this present tendency of ever increasing medical services and the annual expenditure of between £200,000,000 and £300,000,000 which such services necessitate"

How could economy, which was never more important than today, and efficiency in national health, which was never more vital, be achieved? The answer was to be found in that enlightened report of the League of Nations Mixed Committee on Nutrition, 1937 The Medical Research Council had succeeded in condensing the main results into a very few words

"A much greater consumption of milk and other dairy products, of eggs, of vegetables, including potatoes, of fruit, and of fat fish, at the expense of bread, biscuits, sugar and sweets, especially in early life is an urgent national requirement, it will not only improve the physique of the people but will reduce the amount of dental decay and greatly raise the standard of health An increase in breast feeding will still further reduce the high mortality rate of infants from gastro intestinal troubles and bronco pneumonia Whatever advances in medical knowledge may come, until these simple precepts are adopted there will still remain a great deal of preventable disease in this country"

The tragedy was that people did not know how to begin Next to nothing was taught about nutrition in the schools Now that the facts were established the time had come for a great national work of education and propaganda

The task of public enlightenment should not be very difficult The tremendous Governmental machinery on health questions was ready to hand From the cradle to the grave the bulk of the people were accessible all the time to medical advice and instruction The influence of the Government could be powerfully exerted through this machine if a real effort were made

Viscount ASTOR said that the great need was for cheaper and safer milk Up to date the medical profession had not been able to act with complete vigour because it could not be guaranteed that the milk was reasonably safe It was necessary for the Government to see that the milk-supply was safer, and he regretted that proposals towards this end in the Milk Bill introduced last December had been dropped from the present bill Interim reports on the experiment supervised by the Advisory Committee to the Milk Board, of which he was chairman, to ascertain the effects of different milk rations on children, had so far brought out that in growth and weight children who received a single ration of milk improved more than those who got none, that children who got a double ration improved more still, and that there was substantially no difference between giving children raw milk and pasteurised milk This was very important owing to the prejudice in some minds against pasteurisation Farmers were short sighted if they opposed the pasteurisation of milk which did not come from tubercle free cows It was to their interest to get the backing of the medical profession for a "drink more milk" campaign, but they would only get that backing if the milk-supply was rendered safer

Viscount DAWSON OF PENN said the Militia represented all classes, and they would expect to find better average health among them than among ordinary applicant for the Army, partly because Militiamen were sufficiently young to have profited from the improved knowledge of feeding, and partly because ordinary entrants for the Army contained a larger proportion of those down on their luck and not under parental care Above everything else there must be a sure supply of fundamental and protective foods, and a supply of fresh food such as milk, vegetables, eggs and the like Such forms of food were of greater importance to us to grow in this country than corn and cereals, which could be stored but dairy produce and green vegetables must be freshly produced

Was it unfair to say that government after government had been like unto Pharaoh in the obstinacy in regard to the pasteurisation of milk? Outbreaks

of diphtheria and scarlet fever had been proved over and over again to be due to milk

Earl DE LA WARR, president of the Board of Education, said that the value of reports of school medical examinations was to some extent vitiated as there was not as yet any objective or exact method of measuring nutrition or malnutrition. Based on the experimental schemes started in 1936–37 for the supply of milk to mothers and children under five in the Special Areas (from which up to date just over 20,000 persons had benefited, consuming something over a million gallons of milk), it had been the Government's policy since 1937 to secure a reduction of price for milk to local authorities for supplying mothers and children under five. The Government estimated that if they were able to put this reduction in price into operation it would mean an increase in the consumption of milk for this purpose of from something over 3,000,000 gallons a year to something over 20,000,000 gallons a year. The latest figures showed that in England and Wales there were 2,500,000 children paying for their milk in schools, and a further 500,000 were receiving it free.

Replying to a point raised by the Earl of Cork and Orrery, who had said that the operations of the Milk Marketing Board had cost the voluntary hospitals a quarter of a million, and that children could get milk at school but if they went into hospital they did not, Earl DE LA WARR said that they had lately been able to make arrangements for a sick child to call at school for his bottle of milk, or in some cases to arrange for it to be taken to the child's home. He would inquire into the point about hospitals, which was a new one

Last year over 22,000,000 free meals other than milk were provided—more than double the number provided ten years ago School canteens were springing up, particularly in the rural areas, for children who came from a distance, and local authorities were making increased use of their powers to provide free solid meals.

The House to House Collections Bill (formerly the Charitable Collections Regulation Bill) was read the third time, and passed.

QUESTION TIME

JULY 13–19

Chairmanship of Dental Board

Mr WEDGWOOD asked the Paymaster-General, as representing the Lord President of the Council, whether he was now in a position to state whom he had appointed as the chairman of the Dental Board of the United Kingdom — Earl WINTERTON replied: The first chairman of the Dental Board, the late Sir Francis Acland, who died on June 8 last, was appointed in 1921 and reappointed from time to time The period for which he was last appointed would have expired on July 28, 1939, and the provisions of the Dentists Acts preclude the actual appointment of a successor until that date The Lord President, however, has invited Mr. E L Sheridan, F R C S I, L D S I, professor of dental surgery in the National University of Ireland, to accept appointment and Mr Sheridan has accepted the invitation

Mr WEDGWOOD Is the noble lord aware that there is great resentment among British dentists, in view of the Irish hostility towards Great Britain, at the appointment as chairman of the British Dental Board of a Sinn Fein Irish catholic living in Dublin?

Sir FRANCIS FREMANTLE asked whether, inasmuch as the Irish Free State had its own dental board, he would reconsider his decision and nominate a British practitioner for the vacant chairmanship of the Dental Board of the United Kingdom —Earl WINTERTON replied: No, Sir The existence of a dental board in Eire does not seem to the Lord President to be relevant to the question of the appointment of the chairman of the Dental Board of the United Kingdom, one of the members of which, as I would remind my hon friend, must under the provisions of the Dentists Acts be elected by qualified dentists practising in Ireland.

Captain ELLISTON asked whether he would reconsider his intention to appoint a practitioner in the Irish Free State as chairman of the Dental Board of the United Kingdom, in view of the fact that of 14,722 dentists on the British register only 160 practised in the Irish Free State.—Earl WINTERTON replied. No, Sir As my hon friend is aware, Mr. E. L. Sheridan has accepted the Lord President's invitation to succeed the late Sir Francis Acland as chairman of the Dental Board of the United Kingdom. Mr Sheridan, who has been a member of the board for many years, was last elected by qualified dentists practising in Ireland, which expression under the Dentists Acts mean the whole of Ireland, inclusive of Northern Ireland At the date of Mr Sheridan's election the number of qualified dentists on the United Kingdom register practising in Eire and in Northern Ireland were approximately 161 and 285 respectively. I may add that Mr Sheridan's election was unopposed.

Income-tax and Sickness Benefit

Mr. GREENWOOD asked the Chancellor of the Exchequer whether he proposed to take any action with respect to the decision of the Special Commissioners for Income Tax that sickness and disablement benefit from approved and friendly societies, trade-unions and other bodies are liable to income-tax —Sir JOHN SIMON: I saw certain comments on the matter which were communicated to the press this morning, but I am informed that they are materially inaccurate The decision referred to involves no new point of principle at all. Nor is the practice changed. Income-tax, where due in such cases, is not and will not be deducted at the source The actual case was that of a permanently disabled individual with a not inconsiderable private income which is supplemented by substantial payments derived from an insurance company and a friendly society. His total income is much above the exemption limit and the payments, which are treated by the Special Commissioners as in the nature of annuities, have continued for some years It is not the practice to charge benefits for periods of less than a year, no recipient with an income under exemption limits can be affected, and no new field of taxation is opened by the decision I may add that benefits under the National Health Insurance acts and unemployment insurance benefits are not treated as liable to income-tax, nor will they be

In reply to a number of further questions, Sir J SIMON said: There has been no general ruling in regard to income from trade-unions or approved societies This was a particular case decided by the Special Commissioners as a particular case The position is exactly the same as in 1925 or any later year.

Consultant Ophthalmologists for the Militia

Mr RITSON asked the Minister of Labour if he would consider appointing an expert oculist on to the panel of medical boards who were examining recruits for the Militia —Mr ERNEST BROWN replied Each medical board has been given the names of one or more qualified ophthalmologists to whom they can refer men for examination where they consider this to be necessary

In reply to a further question Mr BROWN said the number of references was not sufficient to justify a full-time officer being appointed.

Civil Defence: Surgery Courses

Miss RATHBONE asked the Minister of Health whether he would consider arranging through the appropriate authorities for courses in first-aid war-time surgery to be provided for those medical practitioners whose practice did not normally include such surgical experience —Mr. ELLIOT replied The eminent medical men who are acting as group officers in the various areas, most of whom have had much war-time experience, are I understand selecting doctors with adequate surgical experience for duty in the casualty receiving hospitals I doubt whether the step suggested by the hon member would be of use

Miss RATHBONE: Will the right hon gentleman consider the fact that in war-time practically all the doctors will be busily engaged giving first-aid treatment in bombing areas, and is he aware that the proposal outlined in the question has behind it a good many medical [illegible]

titioners who feel that they had had so little surgical experience that they would be at a disadvantage in time of war even in giving first-aid treatment."—Mr ELLIOT If the hon lady will bring forward any information in her possession I will take it into account

Mustard-gas Blindness

Mr ROSTRON DUCKWORTH asked the Minister of Pensions the number of new cases of blindness by mustard-gas which had been accepted by his department during the last three years, and the number of claims in respect of such disability which had been rejected.—Sir W WOMERSLEY replied Seventy-eight cases of impaired vision, including blindness, due to injury from mustard gas have been accepted (for pension) during the last three years, this figure includes 57 cases in which there has been a previous award for another disability or other effects of gas No claims which have been established as resulting from mustard gas have been rejected

Nursing Committee's Report

Mr ASHTON asked the Minister of Health whether he could now indicate the action it was proposed to take with respect to the recommendations contained in the report of the Interdepartmental Committee on the Nursing Services including the question of superannuation and the transfer of superannuation rights.—Mr ELLIOT replied Yes, Sir With regard to training and education I have already approved amendments by the General Nursing Council of the rules governing the preliminary examination, in accordance with the committee's recommendations These amendments have taken effect, and the President of the Board of Education will in a few days issue a circular on the question of training courses With regard to general conditions of service, I am shortly issuing a circular to local authorities on various recommendations of the committee The question of superannuation, with some other questions, is still under review

Free Meals for Welsh Children

Mr EDWARD WILLIAMS asked the Parliamentary Secretary to the Board of Education the number of children in receipt of free meals and free milk in elementary and secondary schools in the county and county borough areas of Wales and the proportion of the full complement on the registers.—Mr KENNETH LINDSAY replied In May, 1939, 5382 children in public elementary schools in Wales and Monmouthshire, including county and county borough areas and boroughs and urban districts which are local education authorities for elementary education, received free solid meals, 3248 free meals and milk and 60,416 free milk only, 3 1 per cent of the children on the registers received free meals and 18 per cent free milk In the secondary schools free meals and milk are usually given by means of maintenance allowances, but no information is available as to the number of children who receive them in this way

Local Authorities and Hospitals

Mr SILKIN asked the Minister of Health how many hospitals formerly maintained and managed by poor law authorities had been appropriated as public health institutions under the powers contained in the Local Government Act, 1929, and how many of such hospitals were under the control of public-assistance committees.—Mr ELLIOT replied Out of a total of 79 hospitals in England and Wales recognised as poor law hospitals under the terms of the Public Assistance Order, 1930, 61 have been appropriated to public health purposes and 18 remain under the control of the public-assistance committees

Silicosis in South Wales

Mr JAMES GRIFFITHS asked the Home Secretary the number of applications received and the number of certificates granted for total and partial disablement, and certificates that death was due to silicosis among coal miners in the United Kingdom in the 18 months ended to the last convenient date, under the Various Industries (Silicosis) Schemes, and if he would give separate figures for the anthracite coalfield and the rest of the South Wales coalfield; and if he would also give particulars of the grade of employments, and the number of certificates in each grade, respectively.—Mr PEAKE, under secretary, Home Office, replied Applications to the medical board for certificates under the Various Industries (Silicosis) Schemes from coalminers were as follows:—

—	Total	South Wales excluding anthracite mines	Anthracite mines
Disablement or suspension			
Applications for certificates	1306	521	470
Certificates granted	678	275	324
Certificates refused	628	246	146
Deaths			
Applications for certificates	173	89	48
Certified as due to the disease	109	53	28
Certificates refused	64	36	20

The particulars asked for in the last part of the question are not available

British-made X-ray Apparatus

Mr HOPKIN asked the Minister of Health if he was aware that advice was being given to hospitals purchasing deep therapy X ray apparatus that foreign firms could produce better equipment than British firms, and that as a result of this advice several installations of foreign apparatus had been made, and if he would consider issuing a circular to all hospitals recommending them to make use to the utmost extent of the British made X ray equipment.—Mr ELLIOT replied I am not aware that any such advice as is referred to in the first part of the question is being given As regards the second part, my department has issued a circular to local authorities recommending them wherever practicable to make use of goods and materials of home production, but I have no authority to issue a similar circular to voluntary hospitals

---

PLASTIC SURGERY CONGRESS.—The fourth international congress organised by the Société Européenne de Chirurgie Structive will be held in Paris from Oct 5 to 7 The hon president of the congress is Prof P Sebileau, and the president is Dr L Dufourmentel The main subjects for discussion will be the treatment of deformities resulting from scar retraction of the eyelid, and the treatment of deformities of the jaw Further information may be had from the secretaries of the congress, 9 rue de Turin, Paris VIII

EXTENSIONS AT HARROGATE SPA.—On July 10 the Lord Mayor of London opened the extension to the Royal Baths at Harrogate The new building which has been built at a cost of just over £80,000 is capable of providing one thousand treatments a day, all of which use, in one form or another, the natural mineral waters of Harrogate The new wing is connected to the existing buildings by promenades surrounding a central fountain court In place of the old glass covered winter gardens a new lounge has been erected which forms a centre for the whole of the bathing establishment Treatments have been grouped for ease of administration and covered corridors will provide for internal communication between the various departments The entrance and corridors will be free from steps to enable bath-chair patients to have easy access to all parts In the new wing the ground floor contains sulphur baths and the first floor the intestinal lavage department, each with its own dressing rooms, cooling rooms and rest rooms. Elevated tanks containing the various mineral waters are arranged in the water tower which has been placed in a central position for distribution and the hot and cold sulphur alkaline and plain waters are gravitated to the various bathrooms and appliances

Under a new scheme it will be possible for patients to receive medical attention and all baths waters and treatments required for a complete cure are at fixed inclusive charges of 5 guineas for two weeks or 7 guineas for three weeks Hotels in the town are co-operating by quoting reduced fees for patients coming to Harrogate under this new scheme It will thus be possible from the outset for patients to ascertain the exact cost of a cure

OBITUARY

JOHN MELLANBY
MD CAMB., F R S

John Mellanby died on July 15 He was a great physiologist and a great teacher. He was respected by all who knew his work, and loved by his colleagues and assistants

The family was a brilliant one His elder brother is Prof Alexander Mellanby of Glasgow, while his younger brother is Sir Edward Mellanby. The three brothers went to Barnard Castle School, in their native county. At Cambridge John took a first in both parts of the natural sciences tripos, and then became physiologist on the staff of the Burroughs Wellcome laboratories at Battersea, where he joined a group which included Sir Henry Dale and George Barger. After 3 years in this laboratory, he entered Manchester University to complete his clinical studies. His Cambridge M.D. thesis gained for him the Raymond Horton Smith prize, and he spent the next 2 years in the Cambridge physiology laboratory as G. H Lewes student Then, in 1909, when only 31, he succeeded J B. Leathes as head of the physiology department at St Thomas's Here he remained for 25 years, becoming professor in 1920 He was elected an F R S. in 1929, and was a councillor of the Royal Society at his death In 1936 he went to Oxford as Waynflete professor of physiology. He was a fellow of Magdalen, a member of the Medical Research Council and a former editor of *Physiological Abstracts.*

Mellanby always said that work on a new aspect of physiology was a relief and a stimulus to thought In consequence his name is linked with researches over a very wide field. But the connecting thread throughout was always an objective biochemical examination of physiological phenomena At Cambridge he had been a pupil of Langley, Hardy and Hopkins, and the influence of Hopkins was responsible for his interest in biochemistry. His first papers, now regarded as classics, were concerned with globulins and the physical properties of serum. In these Hardy's pioneer work in colloidal chemistry is traceable, and throughout his life Mellanby always emphasised the fact that the body was a series of colloidal solutions, whose properties continually influenced the functions of the organs and tissues

His early work on protein was followed by a systematic examination, with his colleague V J Woolley, of the enzymes of the pancreas The study of lipase led him on to demonstrate the particulate absorption of unhydrolysed fat through the agency of bile salts. He disentangled the parts played by the vagus and secretin in pancreatic secretion. He showed that prosecretin, said to be activated by hydrochloric acid, was a myth, and that secretin itself was present in the duodenal mucosa, thus explaining why achlorhydrics had an adequate pancreatic flow. He purified secretin and showed it to be a proteose, and drew attention to the rôle of bile salts both in secretin absorption and in biliary secretion. The great range of his researches covered also the action of the bladder, the relation of the nervous system to the blood-sugar and glycosuria, the nature of enzyme action, and anoxia, CO_2 carriage and CO poisoning. The pathologist owes him a method of concentrating diphtheria toxin and antitoxin and a way of stabilising colloidal gold for the Lange test. Almost his last publication was on splenomegaly which he produced when studying the function of blood-urease.

But running in and out through this diversity of researches was his work on blood-clotting He showed that prothrombase was not related to platelets, but was a protein in plasma forming a complex with fibrinogen. He investigated the actions of many snake venoms, showing the extreme coagulant effect of viper venom. After the war a much fuller recognition was given to his work, when he isolated and described the properties of pure prothrombase and thrombase, showing prothrombase to be a very labile water-soluble protein. In 1935 he showed that calcium ions were not fundamental for fibrinogen clotting but were made necessary by reason of the peculiarities of the plasma proteins

It will probably be some years before a true assessment of the real value of his scientific work will be made Appreciation of his high place as an investigator has grown slowly but certainly, and there is good reason to believe that even now his great capability is not rated at its true value. He only wrote when he had some outstanding discovery to report He considered himself a general physiologist and was prepared to investigate any problem that interested him It is doubtful whether any other living physiologist, working so often with a lone hand, has contributed so many facts to the science His methods were always simple His experiments were always capable of being repeated by others And repetition has always shown how wise were his conclusions

Mellanby came from the valley of the Tees He was apt to maintain that his name indicated viking origin. Be that as it may, he had a rugged austerity which made him difficult to approach. But beneath this one found a man of extreme shrewdness who had no use for humbug, a first-rate judge of character and a staunch fighter for the rights of the individual. His probity made him a loyal friend and, if he was sometimes brusque in his comments, his candour was justified But over all there was a gift of rapier like wit which never palled and made his friendship a joy This combination of honesty, candour, and humour made John, as he was called by all his students, a power in the land when discipline was called for and routine methods had failed. His lectures were a joy to listen to Every year subjects were approached from a new angle John never repeated himself His Socratic questions, addressed particularly to students in what he liked to call the stalls or the gallery, would often bring down the house He loved figures and would force the ignorant to convert pints of beer into litres of urine He sparkled sitting down and would "doodle" with chalk drawings

crosses inside circles inside squares which tradition said was a test for alcoholic intoxication in one of his earlier researches He was a great examiner and his original questions were designed to pick out of themselves the good and the exceptional candidate He was never afraid to give a high mark when he thought it deserved, sometimes to the surprise of the candidate

Prof A St G Huggett who contributed many of the details for this note recalls the joy it was to meet Mellanby and his wife and daughter Joan in their home at Englefield Green Mellanby got immense pleasure out of achievement of any kind, especially if this was associated with beauty His knowledge of and skill in gardening was very great Any free time in London often brought him to Christies, where he would purchase some beautiful but inexpensive example of craftsmanship and bear it home rejoicing to show to his family and intimate friends He bought articles because they pleased him and then proceeded to study the subject they represented His knowledge of antiques thereby became great He was, however, no showman, and his vivid interest in and knowledge of life was only appreciated by those who were closely associated with him

LETTERS TO THE EDITOR

OPHTHALMIC BENEFIT

SIR,—May I draw attention to the new developments that are taking place with regard to the administration of ophthalmic benefit under the National Health Insurance scheme Some years ago the British Medical Association entered into arrangements with the Association of Dispensing Opticians to form the National Ophthalmic Treatment Board (N O T B) The B M A.'s reason for this step was to encourage insured people and others of similar income status to consult a medical practitioner rather than a sight testing optician To this end very extensive propaganda and advertisement have been undertaken by the board, and the number of insured people availing themselves of the facilities offered is now so large that the N O T B look forward with confidence to the absorption of practically all ophthalmic work of this type Hitherto any practitioner who could show "reasonable ophthalmic skill" has been eligible on application to have his name included in the list of doctors operating the medical aspect of the scheme, and no body has had power to exclude any suitably qualified medical practitioner After a considerable agitation some twelve months ago the Ophthalmic Group Committee of the B.M.A. was made representative, but the medical representation on the N O T B remains largely executive, being directly elected by the group committee

It is important to recognise that the commercial side of the N O T B has received criticism It is not clear to everyone that the charges for spectacles under the scheme are equitable to the public in all the circumstances, and some have thought it undesirable that patients should be directed to ask a tradesman to arrange for them to see a doctor, especially as the tradesman is subsequently to sell them goods ordered by the doctor selected Others have found derogatory the keeping of ophthalmic appointments made by an optician in premises owned by that optician, and some doubt has existed both among medical practitioners and dispensing opticians as to whether such patients really belong to the dispensing optician or to the doctor, since the dispensing optician pays for the advertisement and provides the whole of the money for the N O T B organisation, by a levy on sales under the scheme

The N O T B is now to be made into a limited company, to protect its title, but advantage is being taken of this opportunity to alter the status of practitioners coöperating under the scheme We are invited to sign "form A" which is "an application for appointment for the conduct of ophthalmic examination and treatment on behalf of the N O T B Ltd" It is possible that the words "for appointment" may be changed to "to have my name placed on the list of practitioners approved for" The operative clause here is "on behalf of." The wording recognises the proprietary right of the N O T B in the goodwill involved The ophthalmologist thus asks to be permitted to see patients entitled to benefit under national health insurance "on behalf of" a limited company who, by advertisement and propaganda, have persuaded patients to place their ophthalmic destiny in their hands

Not content with forcing an existing practitioner, whose livelihood depends to a greater or less extent on the N O T B, to seek an appointment, the form requires him "to observe the conditions, rules, and regulations laid down by the B M A. from time to time" Insurance practice in ophthalmology is for the future to be dependent on our submission to conditions imposed by the B M A Further, this section authorises the Ophthalmic Group Committee of the B M A. "after due inquiry to take such action as it may consider appropriate in the circumstances" Such disciplinary action might well include expulsion There is no provision for appeal The next clause reads, "I agree to the condition that my appointment is terminable by one month's notice in writing on either side"

The final arbiter of our professional destiny is thus to be a limited company, whose board consists one-half of opticians, and which may terminate the appointments of its oculists just as it dismisses its errand boys—on one month's notice—such notice being of the same significance to an oculist as would be a similar termination of his panel practice to any general practitioner It is essential to the scheme that the names of all qualified ophthalmic practitioners must be submitted to every patient applying to be seen under the scheme The last paragraph reads, "I agree that failure on my part faithfully to carry out the above provisions or undertakings gives to the Ophthalmic Group Committee of the B M A full power to direct the N O T B to erase my name from the N O T B Ltd ophthalmic list" So that not only may his livelihood be taken away, but he may be for ever excluded from participation in the huge advertisement given to his more fortunate or more amenable colleagues A resolution proposing to include in form A a recognition that the case-records of patients seen are the property of the doctor, not of the optician, was passed at the general meeting of the ophthalmic group of the B M A on Friday last

The N O T B found its inception in the desire to provide a national ophthalmic service for the masses Due credit must be given to the B M A for the arduous pioneer work But the position at present is that a vast commercial enterprise has developed with

all the machinery of expensive advertisement, and this organisation is now in the position of a disciplinary body over ophthalmologists, whom indeed it is to employ in future. It is true that this commercial organisation is not to act without professional restraint, but it is questionable whether it serves a national or professional advantage to have a commercial organisation exercising such powers It must still be the object of ophthalmologists to organise a national eye service, but if the financial arrangements necessary for such a service cannot be developed by the profession, it seems to most of us that it would be more reasonable to have some public body in charge of such arrangements. The introduction of commercial interests into any national scheme of this kind would be regrettable at any time. When such a commercial organisation now seeks to exercise disciplinary action, the time has come to review the whole basis upon which a national ophthalmic service can function best.

I am, Sir, yours faithfully,

R LINDSAY REA,
President, Association of British Ophthalmologists

Harley Street, W 1, July 17

ABDOMINAL RESECTION FOR RECTAL CANCER

SIR,—Possibly comments aroused by Mr. E. G. Muir's article in your issue of May 13 will have come and gone by the time this letter reaches you, but I should like to welcome his paper as a sign of growing attention to the more "selective" procedures (to use a thoracoplastic analogy) in rectal cancer

The subject was discussed at the tenth Australian and New Zealand Cancer Conference held in Wellington last February, and in the course of a paper on conservative surgery in cancer of the rectum I referred to the pathological research of Westhues, about 1930, the recent St Mark's survey, and the clinical applications of these matters by such surgeons as Gehrels, Goetze, and Devine My own small personal series of 14 operable cases of rectal cancer fell into the following groups :—

(*a*) In 5 cases conservative resection was impossible because of the low situation of the growth.

(*b*) In 2 cases in which the anus was sacrificed, it might have been possible to save it in the light of more recent views.

(*c*) In 2 cases Hartmann's abdominal resection was carried out with permanent colostomy, but in cases similar to these occurring now I would attempt conservation of sphincter

(*d*) In 4 cases conservative resection (2 sacral and 2 abdominal) was carried out.

(*e*) In 1 case, very suitable for abdominal conservative resection, the procedure was not completed.

Thus half of the 14 cases had, or were suitable for, conservative resection. Similarly, in reviewing 26 radical combined operations at Auckland Hospital, I judged that 17 (or 65 per cent.) were suitable, on anatomical grounds, for saving of sphincter. Continental surgeons give high percentages of conservative resections—e g , Hochenegg 25, Kuettner 42, Finsterer 70 (quoted by Gehrels).

Mr Muir does well, therefore, to call attention to possibilities other than the standard perineal, perineo-abdominal, and abdominoperineal procedures. The basis for the conservative operations, with saving of sphincter, lies in the proven rarity of downward and lateral metastases, and its success has been made more general by improvements in technique, conspicuous amongst which I would place Devine's double-barrelled colostomy, and total "defunctioning" and disinfecting of the distal colon segment bearing the growth

I am, Sir, yours faithfully,

Auckland, N Z , June 29 DOUGLAS ROBB

THE MANTOUX TEST

SIR,—In recording the results of Mantoux tests there is at present to my knowledge no concise way of doing so to show both dose and reaction It seems important that when these tests are repeated at intervals—e g , contacts, nurses in institutions—and perhaps by different medical officers, changes in sensitivity should be readily noted Hence the need for recording not simply a negative or positive reaction but both the dose and the reaction to it To make this recording concise I suggest the following.—

A. Record doses as follows .

1 mg as 1	0 01 mg. as 3	1 mg =1 is the important
0 1 mg as 2	0 001 mg as 4	figure from which to derive the others.

B Record reactions on the lines of the Aronson scale:
Aronson 0 and ? (reaction less than 5 mm) as 0.
Aronson + (reaction between 5 and 10 mm) as 1
Aronson ++ (reaction between 10 and 20 mm) as 2
Aronson +++ (reaction over 20 mm) as 3
Aronson ++++ (central necrosis) as 4

C. Record results of the Mantoux test as dose × reaction —e g , 0 01 mg O T giving a ++ reaction would be shown as 3×2

No virtue is claimed for the actual mathematical product, but it is suggested that the expression of dose and reaction as shown above has the merits of simplicity for the purposes of recording, and would show at a glance any significant change in reaction.

I am, Sir, yours faithfully,

R. S R FRANCIS.

Mecklenburgh Square, London, W C 1, July 11

LEUCO-ERYTHROBLASTIC ANÆMIA

SIR,—Hæmatologists have often been accused of complicating the terminology of their subject to such an extent as to make their specialised literature almost incomprehensible to the general physician and even to the majority of laboratory workers Interest in the nomenclature of blood-cells has waned very considerably since the death of Pappenheim, who did so much to differentiate between cells on the basis of minute tinctorial peculiarities ; but, even at its worst, such specialised researches were nothing more than the hobby of some hæmatological laboratory workers. More recently the interest has shifted from the classification of cells to the classification of "blood diseases," which, instead of being regarded as hæmopoietic reactions—as in most cases they are—have been hypostatised into maladies sui generis

This unfortunate tendency is exemplified in Dr Lucey's report in your issue of July 8 , for he suggests that "some cases of so-called acquired acholuric jaundice may really be unrecognised cases of leuco-erythroblastic anæmia," and he begs that we take care to exclude "the latter *disease* by a thorough search of the body for a primary malignant growth and by radiography of the bones for secondary deposits ." (my italics) Surely what is meant is that the discovery of a leuco-erythroblastic blood

picture is to be regarded as an indication for careful search for one of the known causes of such a change, and one of the known causes is the presence of metastases in the bone marrow There is no basis on which it can be claimed that leuco erythroblastic anæmia is a "disease", any more than it could be contended that the hypochromic anæmia that develops in cases of gastric carcinoma is a "disease" The blood is not a tissue but a mixed secretion, derived from various organs, which themselves may be the seat of disease Changes in the blood, like changes in the urine, are symptomatic and nothing more

My protest against the elevation of leuco erythroblastic anæmia to the status of a disease is, I think, important, because Lucev's article suggests that the absence of secondary deposits in the bones would make him revise his diagnosis of leuco erythroblastic anæmia The position is surely that leuco erythroblastosis is nothing more than the name applied to a special sort of blood picture The cause may be obscure, but even if it is not detected, the blood picture still deserves the same name

I am, Sir, yours faithfully,

Harley Street, W 1 July 11 A PINEY

SUNSHINE AND MENINGITIS

SIR,—Your issue of June 10 contains a letter from Dr Douglas Hubble on Sunshine and Meningitis When I was senior medical officer at the Nkana Mine in Northern Rhodesia in 1930 I had six cases of cerebrospinal meningitis in Europeans, and of these patients three were people who were known to go about regularly without hats Though six cases is an insufficient number on which to form any opinion, it struck me at the time that undue exposure to tropical sun might be a predisposing cause, and this appears to agree with Dr Hubble's theory, which certainly seems to be worth further inquiry

I am, Sir, yours faithfully,

Nanyuki, Kenya Colony July 8 G DUNDERDALE

THE PROBLEM OF MEDICAL LITERATURE

SIR,—With further reference to the discussion initiated by Prof McDowall, I should like to draw attention to a bibliographical tool not hitherto mentioned—namely, the "Subject Index to Periodicals," which includes the principal British medical journals among the 600 periodicals indexed It is published annually in one volume by the Library Association, and reference may be made to it at all university and most public libraries

The "Subject Index" is on the dictionary catalogue plan Entries are classified under specific subject-headings, which facilitates quick reference, and connexion is maintained between allied subjects by a system of easily understood cross references

The problem of obtaining access to any particular periodical is largely solved by the "location list" appended to each volume In this list—which is believed to be at present a unique feature in periodical bibliography—the periodical holdings of more than 170 national, municipal and institutional libraries are set forth in tabular form

I write in the hope that the "Subject Index to Periodicals," which has been functioning since 1915 along the lines indicated by previous correspondents, will prove of some value as a practical starting-point I am, Sir, yours faithfully,

T ROWLAND POWEL,
Editor, the Subject Index to Periodicals.

Chaucer House, Malet Place W C 1 July 17

HAVELOCK ELLIS

SIR,—Your obituary of Havelock Ellis emphasises his work in encouraging an enlightened attitude towards sex It refers only in passing to what must surely be considered the wider meaning of his life and work, his belief in the "basic identity of science and mysticism" It is as well to remember that to this clear thinker mystical experience was as "real" as the data of physiology or physics, for an unreal dichotomy in human experience is popular today, emphasised often by the partisan warmth of those who can see no other frame of reference than their own

Medicine at the moment pays at any rate lip-service to the concept of psychosomatic unity For a greater understanding of this, Havelock Ellis's *Weltanschauung* contains much that is of special value to us

I am, Sir, yours faithfully,

Kenneth Court, S E 11, July 16 C W M WHITTY

BLOOD-GROUPING OF THE POPULATION

SIR,—May I make a plea for a general grouping of all the population, into their blood groups, so that in the event of hostilities it would be an easy matter to supply blood of a suitable group to the injured person Also, it would be known where universal donors could be found quickly, or where universals could form a blood-bank for general use This would also be of value in cases of accidents, road or otherwise, for any hæmorrhagic emergencies

This could be arranged, either by the people attending at a pathological laboratory of a large county hospital, or the county medical officers of health I am, Sir, yours faithfully,

Lewes, July 12 J NICHOLL

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 8, 1939

Notifications.—The following cases of infectious disease were notified during the week Smallpox, 0, scarlet fever, 1870, diphtheria, 892, enteric fever, 32 (50 "expected"), pneumonia (primary or influenzal), 452, puerperal pyrexia, 209; cerebro-spinal fever, 32, acute poliomyelitis, 15, acute polio-encephalitis, 1, encephalitis lethargica, 5, relapsing fever, 1 (North Westmorland R.D), dysentery, 42, ophthalmia neonatorum, 91 No case of cholera, plague or typhus fever was notified during the week

The number of cases in the Infectious Hospitals of the London County Council on July 14 was 3000 which included Scarlet fever 750 diphtheria 546 (carriers, 18) measles 19 whooping-cough 787 puerperal fever, 20 mothers (plus 9 babies) encephalitis lethargica 306 poliomyelitis 6 At St Margaret's Hospital there were 20 babies (plus 10 mothers) with ophthalmia neonatorum

Deaths.—In 126 great towns, including London, there was no death from smallpox or scarlet fever, 1 (0) from enteric fever, 7 (0) from measles 10 (3) from whooping-cough, 28 (5) from diphtheria, 10 (11) from diarrhœa and enteritis under two years, and 10 (0) from influenza The figures in parentheses are those for London itself

Northampton reported the only death from typhoid Gateshead had 3 deaths from measles Birmingham 2 Birmingham also reported 2 deaths from whooping-cough Fatal cases of diphtheria were scattered over 20 great towns Luton Bradford Hull Leeds Liverpool and Manchester each reporting 2

The number of stillbirths notified during the week was 203 (corresponding to a rate of 40 per 1000 total births), including 12 in London

MEDICAL NEWS

University of Oxford

At a congregation on July 15 the following degrees were conferred :—

D M—W H Brown and R McDonald

B M, *Ch.B*—George Ashforth, J W Ashley, J F. Bourdillon, J T Burrowes, N F E Burrows, J W B Douglas, E S Elliott, F Fulton, S J S Hughes, R M Lattey, J A L Leeming, G K McGowan, J. N Mills, E S Nicholson, M M. Pickles, W A H Stevenson, T Sutton Coulson, S F Taylor, G Theophilus, G D Walker, G F Walley, and R T Warren

Staines Medical Research Fellowship—This fellowship which has an annual stipend of £400 is tenable at Oxford for a maximum period of five years It is open to candidates of British birth who are more than 35 They should preferably hold a registrable medical qualification. An election will be made in the course of the Michaelmas term and further information may be had from the rector of Exeter College.

University of Cambridge

A scholarship of the annual value of £100 or £60 is offered at Peterhouse to candidates who intend to study medicine It is open for competition by an examination to be held in December, 1939, and may be awarded for proficiency in mathematics, classics, natural sciences or history Particulars may be obtained from the tutor of the college.

University of London

At recent examinations the following candidates were successful :—

G W Boden, M L Mundy, Mohamed Nasiruddin, and Peggy C Permain

University of Birmingham

At a congregation on July 1 the following degrees and diplomas were conferred .—

Ph D—Stuart McDonald, M B

M D—C H Catlin

M D (State Medicine)—D F McCarthy and J V. Walker

M B, *Ch B*—P H Davison and B A E. Johns (first-class honours), P W W Gifford, P F J Hickinbotham, and Y D Williams (second-class honours); G M Barling, G H Boston, Anna R Burrows, H R Chapman, J S I'A Chesshire, Agnes H Crozier, Doreen Davies, Margaret B Davies, J A Duncan, T B FitzGerald, D C Galloway, A A Gattas, V. B Goldman, Marion W S Green, Paul Harris, D S Johnson, Harry Kenyon, Elizabeth B Lindsay, W K Lloyd, D J Macmillan, Lothar Marx, Percy Morrell, Margaret A Norton, D G Richards, Eleanor M Sawdon, Dorothy W Smith, E T M Smith, D H Thompson, and Margery B Webb

B.D S—J L Hardwick.

Diploma in Dental Surgery—H P Britten, B G Davies, I H Jones, John Kitchen, A J Vaughton, D E Wallis, and E W Wiley

University of Sheffield

Dr. Wilson Smith has been appointed to the chair of bacteriology in succession to the late Prof J. W Edington.

Dr Wilson Smith, who is 42 years of age, was educated at Accrington Grammar School He enlisted in the Royal Army Medical Corps in 1915, and served in France and Belgium with the 107th Field Ambulance B E F from 1916 to 1919 After the war he studied medicine at the University of Manchester and graduated M B in 1923 He spent several years in private practice and in 1926 took a postgraduate course in bacteriology The following year he obtained the diploma in bacteriology of the University of Manchester and was appointed research assistant to the director of the department of experimental pathology and bacteriology at the National Institute for Medical Research In 1929 he obtained the M D Manc., with commendation and joined the scientific staff of the institute, and in 1931 he was promoted to the senior grade of the staff In 1934 he was also appointed one of the editors of the *British Journal of Experimental Pathology* Dr Wilson Smith has published many papers, some in our own columns, on his investigations into the nature of viruses and virus diseases in general, on methods of standardisation and assay of anti-pneumococcus sera, and on the investigations of influenza pursued at the institute

Mr W. J. Lytle has been appointed hon lecturer in surgery to dental students, and Dr Andrew Wilson assistant lecturer in pharmacology.

The L C.C. and King's College Hospital

There is great need for additional hospital bed accommodation in South London, and the L C C. therefore propose to accept the offer of King's College Hospital to place a ward at the council's disposal. The council has already decided to erect a new hospital in South London, but this is unlikely to be available before 1942.

Royal College of Surgeons of England

A quarterly meeting of the council was held on July 13 with Mr Hugh Lett, the president, in the chair. Mr. Lett was re-elected president, and Sir Robert Kelly and Sir James Walton were elected vice-presidents for the ensuing year. Sir James Walton was readmitted, and Mr R J. Willan and Mr. Cecil Joll were admitted to the council Dr. Donald Balfour (Mayo Foundation) and Prof Peter Bull (Oslo) were admitted as honorary fellows The John Tomes prize was presented to Mr Arthur Bulleid and the Hallett prize was awarded to Mr W. M. Beattie Mr. F H Mills was appointed a Leverhulme scholar for three months. The tenth Macloghlin scholarship was awarded to R. H Gorrill of Torquay Grammar School

The following were elected for the ensuing year :—*Hunterian professors*. Dr S A Henry, cancer of the scrotum in relation to occupation; Mr. C P G Wakeley, treatment of certain types of external hernia, Mr Digby Chamberlain, treatment of stone in the common bile-duct, Mr. Rainsford Mowlem, use and behaviour of cartilage and bone transplants, Mr. Hermon Taylor, clinical evaluation of gastroscopy; Mr E C. B Butler, treatment, complications and late results of acute hæmatogenous osteomyelitis, Mr A H. McIndoe, inlay grafting, Mr. T F. Todd, urological complications of carcinoma of the cervix; Mr D. L Griffiths, Volkmann's ischæmic contracture; Mr F. F Rundle, the pathogenesis of thyrotoxicosis—clinical aspects, Mr. Kenneth Eden, dumb-bell tumours and neurofibromatosis of the spine, and Mr. F H. Mills, pathogenesis of thyrotoxicosis—experimental aspects. *Arris and Gale lecturers* : Dr John Beattie and Mr M W. C Oldfield *Erasmus Wilson demonstrators* Mr Robert Davies-Colley and Dr L W. Proger. *Arnott demonstrator*: Dr. A J. E Cave.

Dr L W Proger was reappointed pathological curator of the museum, Sir Frank Colyer, hon curator of the odontological collection, and Mr. C J. S Thompson, hon curator of the historical collection Prof G Grey Turner was appointed representative of the college on the council of King's College, Newcastle The following were appointed assessors for the primary fellowship examinations to be held abroad next year :—

India—Prof M A H Siddiqi (anatomy) and Lieut.-Colonel H S Anand (physiology)

Egypt—Prof Douglas Derry (anatomy), Prof G Von Anrep (physiology), and Dr Boris Boulgakov (superintendent of dissections)

Diplomas of fellowship were granted to the following :—

J R Dickinson, Camb and Guy's, G H Baines, Camb and St Thomas's, F J Cahill, Melb, F E Stock, King's Coll., and Y M Subhedar, Bombay.

A diploma of membership was granted to P. W W Gifford (Birmingham), and licences in dental surgery to the following .—

J D Anderson, M S Barrada, P G Berger, B A Bharucha, Hubert Brock, A N Butler, I S. Cardell, F A Clements, T N G Copestake, P W Davis, D H Davy, D B Doran, J A. Dosser, J C Douglas, A R M Fakhry, J. C M Flower, R J Gething, I K Gooch, L M Irwin, M R C Kemp, Alan Kinghorn, W B Knapman, B R S Leake, D W Macleod, G A. McMurdo, L D C March, D D Mears, Arnold Mowbray, D C Murray, J M Paterson, R H F Pearce, H R Phillips, T N Praat, Heinz Rawitz, G G G Rees, Howell Rees, J. G Richards, R E Savage, E W Sleeman, H V Spence, M A. Tischler, G M Turner, Emmerich Weindling, and G A M Whittall

The following diplomas were granted jointly with the Royal College of Physicians .—

D P H—L A Collins, E A Hardy, H B Hodson, S B Karani, S A Maclean, Margaret M Meikle, Joseph Moraza, and Kathleen M N Vickers

D P M—Rosie B Becker, F A Bleaden, Neville Copelyn, W A S Falla, S W Gillman, F P Haldane, F D S Hatfield, J A Herd, J H Hurt, H A C Mason, Elizabeth H Rosenberg, C A Rumball, J P Spillane, Joyce M Stephen, G T Stockins, F J E Stuhl, S Le R Switzer, J A Walters, and Fanny D Wride

D L O—O I E De Sousa, T P Hardie Nell, S W G Hargrove, J F Jarvis, F J Kritzinger, L F Lal, K G Rotter, A S Shereen, Jagdish Singh, T P N Sinha

University of Manchester

Dr David Stewart, lecturer in anatomy, has been appointed assistant director of the anatomical laboratory Dr T E. Barlow and Dr Sidney Mottershead have been appointed demonstrators in anatomy

Dr T H B Bedford, Dr William Brockbank, Dr F R Ferguson, Dr P B Mumford, Dr J F Ward, and Dr Raymond Whitehead have been appointed members of the board of the faculty of medicine

Westminster Hospital

The annual dinner of the old students of this hospital will be held on Saturday, Sept 30 at the Trocadero Restaurant, London W 1 Dr Hildred Carlill will be in the chair Lord Burghley, M P, will deliver the inaugural address of the session on Monday, Oct 2, at 3 P M

International Society of Medical Hydrology

The next annual meeting of this society is to be held in Florence and the neighbouring spas from Oct 14 to 19 The members of the congress will be housed in Montecatini for the first four days, and in Salsomaggiore for the fifth, but the opening meeting will be held at Florence Subjects for discussion will be physicochemical studies of the perspiration occurring after treatment by peloids, spa treatment of diabetes, and the action of solar rays on the skin of children Further information may be had from the secretary of the society, 22, Bedford Place, London, W C 1

Crops and the Soil

In the course of an address to the Society of Chemical Industry this week Sir John Russell, F R S, director of the Rothamsted Experimental Station, referred to the effect of manuring on the quality of crops Some people, he said, went so far as to claim that crops grown with inorganic fertilisers were themselves unhealthy, were unwholesome for human beings and for animals, and conduced to disease, whereas crops grown with organic manures remained healthy and health giving "No evidence is offered," he added, "nor do I know of any All available evidence goes to show that the large crops grown with suitable fertiliser mixtures are at least as healthy and as nutritive as any others"

International Neurological Congress

The third International Neurological Congress will be held in Copenhagen from Aug 21 to 25 under the presidency of Prof Viggo Christiansen The main topics for discussion will be the endocrine vegetative system, the heredo familial diseases, and neurological aspects of the vitamin deficiencies Sir Henry Dale, F.R S, will contribute a paper to the first discussion, and Sir Edward Mellanby, F R S, and Dr C C. Ungley will speak in the third discussion

The congress will also meet in various sections, one of which will deal with neurological subjects and one with epilepsy Further information may be had from the secretary of the British national committee, Dr Macdonald Critchley, 137, Harley Street, London, W 1

Imperial Social Hygiene Congress

A dinner for this congress was given on July 13 at the May Fair Hotel, London, by the British Social Hygiene Council Dame Rachel Crowdy, proposing the toast of Health and Education in the Empire, paid tribute to Havelock Ellis, as one of the greatest pioneers of sex hygiene She went on to speak with some misgiving of conditions in the West Indies which she had lately visited as a member of the Royal Commission In some parts, she said, ten or fourteen people are living in rooms measuring only 10 × 12 feet, and there is little teaching and amusement for adolescents The only preventive work she saw in Trinidad concerned the immunisation of bananas at the Tropical School of Agriculture Sir Walter Langdon Brown proposed The Guests and recalled that Dr Gordon Bates, the general director of the Health League of Canada, supervised the film "Damaged Lives" which has now been seen by over 5 million people in this country Dr Bates, in reply, said that social hygiene means essentially an emphasis on the social responsibility that each man and woman in the world has towards every other man and woman He spoke of the need for consistent propaganda through the radio, the newspapers, and otherwise In referring to some of the achievements of the Health League of Canada, he remarked that last year out of 1000 pregnant women successively examined only 3 had a positive Wassermann reaction The conquest of diphtheria, he said, rests entirely on education, the method of prevention exists but is not being used In Toronto in the course of four years the incidence of this disease fell from 1022 cases with 65 deaths to 22 cases and no death This year there had been only 2 cases in Toronto, a city of 800,000 people Compared with this in Great Britain last year there were 62,000 cases of diphtheria "Raw milk," continued Dr Bates, "has caused more deaths than war itself," and yet France, the home of Pasteur, does not pasteurise her milk In Toronto in the first year of pasteurisation the infantile mortality fell by 30 per cent and bone tuberculosis of bovine origin vanished Compared with this in Glasgow one hospital is devoted to the care of this form of bone tuberculosis Dr J M Mackintosh paid tribute to the health work stimulated by Mr L S Amery, as president, notably the inclusion of venereal diseases treatment in Mr Lloyd George's health insurance scheme

Cosmetics

A plea for more serious attention to the medical aspect of the cosmetics industry was made by Mr H Stanley Redgrove addressing the annual meeting of the Society of Chemical Industry at Exeter on July 12 "Unfortunately," he said, "medical men have been too engrossed with combating the ills which cause death to devote attention to those which produce merely ugliness Hence the story of curative cosmetics is largely a story of chicanery" It was difficult for a woman to judge of the merits of a cream whose persistent use, it was claimed, would restore a lost complexion The task was one for the dermatologist "There is, in my opinion, only one satisfactory method of evaluating a cream for which permanent beautifying effects are claimed Of a series of subjects, one half of the face must be treated over a sufficient period with the cream in question, and the other half, for the same period, with a cream identical in composition with the first cream save for the omission of the special ingredient whose action is under investigation It is practically impossible to persuade women to carry out rigorous tests of this character They can be done in hospitals only"

Births, Marriages and Deaths

BIRTHS

DEWSBERY.—On July 9 at the London Clinic, the wife of Dr J P Dewsbery—a daughter

DIVINE.—On July 11, at Singapore General Hospital the wife of Dr T A Divine—a daughter

HALL.—On July 9 at 174 Sutherland Avenue, W 9, to Marcia, wife of Dr Vernon Hall—a daughter

NELSON.—On July 10 at Bournemouth, the wife of Dr Wallace Nelson Gold Coast—a son

MARRIAGES

KEKWICK—PEARCE BROWN.—On July 8, at Holy Trinity, Brompton, Alan Kekwick M B M R C P, to Susan Pearce Brown

MOLESWORTH—MOORE.—On July 15, at St Albans Abbey Brownlow David Molesworth M B to Rosemary Katharine Moore

YOUNG—HOOPS.—On July 4 at St Jude's Church Courtfield Gardens London, Bertram A Young M D M R C.I, to Betty M Hoops

DEATHS

DEWES.—On July 13 at Blackheath Frederick Joseph Dewes M R C S, lieut-colonel I M S (retd), aged 83

DYSHORT.—On July 14, at Camberley Surrey, Donald Frederick Dysnort major, I M S (retd), aged 53

HUNT.—On July 14 Ernest Rivaz Hunt M D Camb, M R C P of 14, Palmeira Avenue, Hove, senior aged 66

MELLANBY.—On July 13 John Mellanby M D Camb, F I S Wycliffe professor of physiology and fellow of Magdalen College

PHILPOT.—On July 11 at 19 Campden Hill Square W 8 Joseph Henry Philpot M D Lond, M R C P in his 89th year

N.B.—A fee of 7s 6d is charged for the announcement of Births Marriages and Deaths

Appointments

ASPIN, D E, M B Glasg, assistant medical officer of health (A R P) for Blackburn
BAILLIE, M HAYDON, M R C S, resident medical officer at the Borough General Hospital, Warrington
CLARK, J M P, M B Leeds, F R C S, medical superintendent at the Marguerite Hepton Memorial Orthopædic Hospital, Thorp Arch, Yorks
CRABB, D R, M B Lond, surgeon to the City of London police force
FORDF, NANCY, M B Manc, junior assistant medical officer at the Wadsley Mental Hospital, near Sheffield
GREEN, H J, M B Aberd, F R.C S E, registrar and obstetrical tutor at the Jessop Hospital for Women, Sheffield
HASLEGRAVE, IRENE, M B Leeds, resident medical officer at the York Dispensary
HEAP, M J McKENZIE, M R C S, resident house-surgeon at Royal Manchester Children's Hospital, Pendlebury
HILL, B. P, M B Manc, D P H, hon assistant anæsthetist to the Royal Berkshire Hospital, Reading
HUDDY, E C H., M B Lond, D P H, assistant medical officer of health for Finchley
HUGHES, EDWARD, M D Lpool, D P H, medical officer of health and port medical officer for Dover
JONES, J D T, M B Durh, junior surgical registrar at the Royal Victoria Infirmary, Newcastle-on-Tyne
LENDRUM, J D, M B Manc, D P H, assistant county tuberculosis officer for Worcestershire and resident medical officer at King Edward VII Memorial Sanatorium, Knightwick
LYLE, J S, M B Edin, F R C S E, resident surgical officer at the Royal Infirmary, Bradford (reappointment)
MURPHY, J M, M B Dubl, D P H, resident assistant medical officer at the City Isolation Hospital, and temporary assistant medical officer for Cardiff
O'GORMAN, F J P, M B Glasg, senior resident officer at the Jessop Hospital for Women, Sheffield
ORTON, ROBERT, M B Leeds, assistant medical officer at Storthes Hall Mental Hospital, Kirkburton, near Huddersfield
OWENS, W E, M B Camb, D A, hon anæsthetist to the Hospital for Women, Soho Square, London
PAYNE, R W, F R C S E, D O M S., hon surgeon to the Royal Eye Infirmary, Plymouth
ROWLANDS, E N, M D Manc, resident medical officer and assistant pathologist at the Royal Infirmary, Bradford
SAXTON, R S, M R C S, assistant medical officer for civil defence for Brighton
WAYTE, A B, M R C S, chief clinical assistant to the X-ray (diagnostic) department of the West London Hospital
WOODHEAD, ALICE L, M D Manc, M R C O G, consulting gynæcologist for Hackney
WYNTER, TAMSIN, M D Lond, D A, hon anæsthetist to the Hospital for Women, Soho Square, London

Charing Cross Hospital, London—The following appointments are announced—
JAMES, K L, M S Lond, F R C S, cancer and radium registrar,
REYNOLDS, S R, L R C P, clinical assistant in the X-ray and electrotherapeutic department; and
BURFORD, H G, B M Oxfd, clinical assistant in the dermatological department

London County Council—The following appointments are announced A M O (I) or (II)=assistant medical officer, class I or class II—
SMELLIE, ELSPETH W, M B Oxfd, A M O (I), White Oak,
LEGGETT, H A, M B Lond, A M O (II), Grove Park;
MCDOWELL, L A, M B Belf, D P H, A M O (II), King George V Sanatorium,
MEAGHER, MARY W, M B N U I, D P H, A M O (II), White Oak,
SHARKEY, JOSEPH, M B Dubl, A M O (II), Archway;
FLETCHER-JONES, H C, M B Lond, A M O (II), Archway,
WYMAN, A L, M B Lond, A M O (II), Archway,
WALSH, J J, L R C P I, D P H, A M O (II), Dulwich,
LEWIS, R I, M D Lond, A M O (II), Paddington,
DAFOE, C S, M D, A M O (II), St Alfege's,
LAWRENCE, J S, M D Edin, A M O (II), St Nicholas';
MILLER, S J H, M B Aberd, A M O (II), St Peter's;
CRAIG, N S, M D Manc, D P H, medical superintendent, St James',
MCCREA, A N, M B Camb, F R C S, senior A M O (II), Highgate and
VERNON, H K, M B Durh, F R C S, senior A M O (II), St Stephen's

Vacancies

For further information refer to the advertisement columns

Belfast Royal Maternity Hosp—Res M O in charge Rea Block (Isolation), at rate of £100 Also two res M O's, each at rate of £52
Belgrave Hosp. for Children, Clapham Road, S W 9—Asst. physician
Benenden, Kent, National Sanatorium.—H.P, at rate of £150.
Birmingham, Dudley Road Hosp—Jun M O, at rate of £200
Birmingham City—Res asst M O, £150
Birmingham City Education Committee—Asst school M.O, £500
Birmingham United Hosp—Asst surgeon to throat and ear dept £50
Blaydon Urban District Council, &c—M O H, £800
Brighton County Borough—Sen. M O. and asst to M.O H., £[illegible]
Bristol University—Asst lectureship in pathology, £300
Burnley County Borough—Asst. M.O, £500
Cambridge, Addenbrooke's Hosp.—H S, at rate of £130.
Cardiff, Isolation Hosp—Asst res M O, £250
Chesterfield and North Derbyshire Royal Hosp—Res surg O, £300
Colchester, Royal Eastern Counties' Institution.—Asst. M O, £35[illegible]
Derbyshire Education Committee—Asst school M O, £500.
Dorchester, Dorset County Hosp—H S, at rate of £150
Dudley, Guest Hosp—Res. surg. O, at rate of £250–£300. Also H S., at rate of £150.
Edinburgh, Princess Margaret Rose Hosp for Crippled Children, Fairmilehead—Sen and jun res surg O's, £200 and £100 respectively
Elizabeth Garrett Anderson Hosp, Euston Road, N W 1—Hon. asst anæsthetist, 10 guineas
Evelina Hosp for Sick Children, Southwark, S.E 1—H.S., at rate of £120
Godalming, Surrey County Sanatorium.—First asst. M.O., £[illegible]
Halifax Royal Infirmary—Cas O for fracture clinic, at rate of £150
Harrogate, Royal Bath Hosp—Res M O., £200.
Henley-on-Thames, Berks and Bucks Joint Sanatorium.—Second res asst. M O., £350
Hull Royal Infirmary.—Second H P. and second cas O., each at rate of £150.
Ilford, King George Hosp—Hon anæsthetist
Ipswich County Borough Sanatorium—Asst M O, £350
Kidderminster and District General Hosp—Sen H S, at rate of £150
Lancaster Royal Infirmary—Cas O and orthopædic H S, at rate of £130
Leeds Jewish Hosp, 9, Leopold Street—Res M O, £200
Lyphook, Hants, King George's Sanatorium for Sailors—Asst M O, at rate of £200
Liverpool Heart Hosp, Oxford Street—H P, at rate of £[illegible] Also clin assts
Liverpool University—Demonstrator in physiology, £300
Maida Vale Hosp for Nervous Diseases, W 9—H P, at rate of £100
Maidstone, West Kent General Hosp—H P and H S, each £[illegible]
Manchester, Ancoats Hosp.—Two H S.'s, one for orthopædics and one for joint post of H S to ear, nose and throat dept., and H P, each at rate of £100
Manchester, Christie Hosp and Holt Radium Institute, Withington—Asst M O, £400 Also res M.O, at rate of £150
Manchester, Royal Children's Hosp, Pendlebury—Res surg O and asst M O for outpatients' dept, each at rate of £150
Manchester, Royal Eye Hosp—Jun H S, £120
Manchester, Saint Mary's Hosp—H S for Whitworth Park Hosp, at rate of £50
Manchester Northern Hosp—Res H P and res H S, each at rate of £100
Manchester Royal Infirmary—Asst surgical officer, £70
Middlesbrough, Poole Joint Sanatorium, Nunthorpe.—Med supt, £900
Ministry of Health.—Medical officers, each £850.
Nelson Hosp, Merton, S W 20—Res H S, at rate of £150
Northampton General Hosp—H S, at rate of £150
Nottingham General Dispensary, Hyson Green Branch—Res M O £300
Oldham County Borough—Temporary asst. M O H., £500.
Penzance, West Cornwall Hosp—H S, at rate of £150
Portsmouth, Saint Mary's Hosp—Jun asst res M O, £[illegible]
Portsmouth Royal Hosp—Cas O, at rate of £130
Preston, Sharoe Green Hosp—Jun asst res M O, at rate of £[illegible]
Queen's Hosp. for Children, Hackney Road, E 2.—H.S and cas O, each at rate of £100.
Reading, Royal Berkshire Hosp—Res anæsthetist, at rate of £250
Royal Army Medical Corps—Vacancies
Royal Free Hosp, Gray's Inn Road, W C 1—Clin asst to gynæcological dept Res cas O, at rate of £150 Also first asst in children's dept, £100
Royal Naval Medical Service—Medical officers
St Mary's Hosp, W 2—Second res anæsthetist, at rate of £[illegible]
Sheffield Royal Infirmary and Hosp—Res H S. to ophthalmic dept., at rate of £80–£120.
Southampton Children's Hosp and Dispensary for Women—Res M.O, at rate of £150
Tavistock Clinic, Malet Place, W C 1—Pædiatrician, £50
University College Hosp, Gower Street, W C 1—Sen asst. radiologist, £250
University of London, King's College, Strand, W C 2—Lecturer in physiology, £350
Wakefield City—Jun asst M O, £500
Walsall General Hosp—Res surg O, £300
Weir Hosp, Weir Road, Balham S W 12—Sen res M O, £[illegible]
West Malling, Kent, Leybourne Grange Colony—Asst res M O, £350
Westminster City—Second temporary asst M O H, £600
Wolverhampton, Royal Hosp—Asst res M O for gynæcological and obstetric dept, at rate of £100
Worcester County and City Mental Hosp, Powick.—Asst M O, £350

The Chief Inspector of Factories announces a vacancy for an examining surgeon at Moffat (Dumfries)

" . One enterprising baby of my acquaintance has already arranged to publish his memoirs in collaboration with a famous psycho-analyst as soon as each of them has learned to write intelligible English "—IRWIN EDMAN in "Philosopher's Holiday," London, 1939

NOTES, COMMENTS, AND ABSTRACTS

THE CULTURAL BACKGROUND OF THE HEALTH EDUCATOR*

BY IAGO GALDSTON, M.D.
DIRECTOR OF THE INFORMATION BUREAU, NEW YORK ACADEMY OF MEDICINE

THE position of the health educator is radically different from that of his associates. His intellectual stance, the working patterns of his mind, are in essentials diametrically opposite to theirs, and properly applied, they serve as correctives.

Who are the co-workers of the health educator? They are those from whom he draws his factual materials, the raw but meaty elements of that which he teaches. They are, to name them singly, the biologist, the physiologist, the pathologist, the medical clinician, the therapeutist, the sanitarian, the vital statistician. (There are also the public health administrators, and the technicians of educational methods and media, but they form a rather different, perhaps secondary, group.) These and many others have one large characteristic in common, which he does not share. They are scientists, whereas the health educator is not. Of course as an individual the scientist may also be an educator, in that he may teach his specialty. The health educator may also be a scientist, or may even attempt to make a science out of his teaching. But this does not affect the basic difference of function. We may say that the health educator and his co-workers look through the opposite ends of the telescope, or, better still, the scientist employs the microscope, the health educator the telescope, the one scrutinises the infinitesimal, the other the universe.

Science has so captivated us that to speak of a professional group as not being composed of scientists almost conveys a stigma. But for my part I intend no derogation of the health educator. On the contrary, I want to dissipate the sense of inferiority that often affects him, and to spare him from aping his at times rather arrogant associates, the scientists, to whom the catch phrase, "Those that can, do, and those that can't, teach," appeals as the quintessence of wisdom.

SCIENCE NOT ENOUGH

There are other functions to be performed besides those of the scientist. One may for example be a philosopher, a person of broad learning, a devotee of *scientia*, of embracive knowledge, intuitionally as well as inductively acquired. At the present time it looks as though the world suffers from a plethora of scientists and a dearth of philosophers. I am certain as to the latter, and the seeming plethora of scientists may only be a reflection of the dearth of philosophers. What does being a scientist imply? It implies first of all the restriction of interest inquiry, and concern to some segment or phase of being, animate or inanimate, individual or universal. It means specialisation, it means isolation and abstraction of that which is dealt with from the rest of existence to which it is related. It means perforce distortion, an attempt at clear definition in terms inherently obscure. It means also the pursuit of a line of endeavour which has yielded powerful means and great knowledge where with to master the environmental world.

I should not be surprised if some took exception to these statements. But I would urge the dissenters to judge science and the scientists by their works. Predominatingly these have been analytical, the large whole has been fragmented, broken into smaller and ever smaller parts, and each part carried further and ever further away from its parent body. Such basically, essentially, unavoidably and desirably are the functions of the scientist, and no one who has any acquaintance with the labours of the bacteriologist, the biochemist, the vital statistician, and the rest of our co-workers will deny this.

Lest some think that in over-compensation for not being of the scientists I gloat in parading their limitations, let me say that I am emphatic only that I may better present the compensating and corrective services which the non-scientific, but I would hope philosophical, health educator must render. The function of the scientist is analytical, that of the health educator is integrative. Perhaps the reason why "all the king's horses, and all the king's men, couldn't put Humpty-Dumpty together again" was because they were all scientists.

The tangent of the scientist's efforts runs to the object of his study, that of the health educator runs ultimately to the individual human being. The scientist may—indeed often must—afford himself the luxury of an uncharted pursuit of his subject, he takes pride in pure science. Not so the health educator, he is functionally committed to practical purposes. He labours for definite ends defined in terms of ever greater human well-being and happiness. The scientist can lock himself up with his rarefied concern, shutting out the to him irrelevant outside world. The health educator must, on the contrary, be ever more embracive in his interest, understanding, and function. The scientist is free to pursue his inquiry wherever it leads him. The health educator is man-bound. The scientist must ask, "is it true?", the health educator in addition must ask "is it pertinent?" The health educator must sift facts and knowledges through the sieve of relevancy to man-kind. For these reasons the scientist need not know what the health educator must.

In contrasting the functions of the scientist and health educator, in setting in opposition their intellectual prerequisites I intend no weighing in balance, and no measuring of merits. I do not know that the one is superior to or more valuable than the other. I do know that they are complementary, and also distinct from each other. I know in addition that many among the scientists look upon the health educator as something of a camp-follower, as a collector of scraps, and a peddler of diluted information. At a more generous level they look upon the health educator as an interpreter or translator of science to the multitude. There are exceptions among the scientists, their number is growing, but withal they are still in the minority. Unfortunately not a few among the health educators share somewhat the same honourless views of their function, and do not fully appreciate the value and importance of their services. Instead of qualifying ever better for their job by cultivating their integrative powers they ape the analytical techniques of their co-workers. They strain at the microscope instead of sweeping the vast horizon with the telescope.

The health educator teaching science instead of well-being, talking to the fact rather than to the man, presents a disheartening picture of energy

* Abridged from an address to the American Public Health Association.

misapplied, of opportunities muffed, and futility and failure eagerly embraced He serves stones to those that ask for life-sustaining bread He mouths a language foreign to those who seek guidance and help He is without a sense of relevancy and has lost his bearings The infertility of much in health education springs from this common confusion as to the rôle and function of the health educator

The health educator is *man-bound*. He cannot afford himself the luxury of pure science. Everything must have reference to man, with the health educator. Every crystallised angular "truth" mined by the scientist must be cut down and polished to fit the peculiar setting, man. Isolated consideration of an established fact is not permissible to the health educator. He must view the fact in its multiple relations, for he is man-bound, and man is a creature of multiple relations. To the scientist the effective cause of syphilis is the spirochæte; to the health educator the spirochæte is only a contributory and at that a secondary cause. To the health educator the prevalence of syphilis depends very largely on dominant motives, on prevailing ideologies, on current objectives in life, if you please, on the prevailing culture in the community. The eradication of syphilis may be sooner effected by a modification of the prevailing culture than by the arsenicals and heavy metals.

In an over-simplified—i.e., scientific—association of ideas it may appear proper and promising to endeavour to stamp out a plague by prohibitive legislation. The non-scientist but philosophic critic, aware of the multiple relations of man, may argue that prohibitive compulsive legislation is seldom effective in attaining the ends sought, and that it always reduces the moral strength of those to whom it is applied.

KNOWLEDGE AND OUTLOOK

The health educator is man-bound: man is his reference point; he must therefore have a comprehensive knowledge of man, of the creature called *Homo sapiens et sentiens*. What does this imply? Some little knowledge of man as a physicochemical mechanism; but a deep knowledge is not essential. The human mechanism is the province of the scientist, who will readily supply the inquiring health educator with the facts desired, which of course must be accepted on faith and in the hope that the scientist really knows whereof he speaks. However, much and deep knowledge the health educator should—indeed must—have of man as a social animal The multiple relations of man are social in origin and nature The health educator confronts man not as a physicochemical mechanism but as a social animal, a creature of the family, and of the community.

Man is a creature with a history—and the knowledge of man as a social animal can be gathered through the keen and critical study of his history. Such knowledge is not to be gained from the standard history-books, most of which are devoted to wars and the exploits of the governing sovereigns and classes It is the cultural history of mankind that the health educator needs to know, beginning at least with the Greeks of the Periclean period.

Man is the builder of an οἶκος, and a maker of tools. A knowledge of the economic and technologic history of mankind is vital to the cultural training of the health educator. Among some groups the economic factor in human existence today overshadows all others and the materialistic interpretation of history is believed to be the only one to afford us a correct understanding of man's motives and actions This is a provincial belief On the other hand, the economic factor in human existence is of tremendous significance, and the lower the subsistence level of the class the greater its operative strength is among them A starving man is of necessity entirely preoccupied with food. The economic factor is a potent catalyst among those of greater fortune, but among them it operates not as a prerequisite to subsistence but as the embodiment of power and prestige. Our much neglected economist and sociologist, Thorstein Veblen, expounded this in his book, "The Theory of the Leisure Class."

The technologic history of man is intimately related to the growth of scientific knowledge, and should be studied in that association The growth of science since the time that Francis Bacon so brilliantly advocated the inductive method of research deserves special study. For gratifying as it is to follow the brilliant and intuitional sorties of Pythagorus, and the more utilitarian works of Archimedes, we *are* the children of modern science. However it is necessary to point out that most students of the history of modern science are too restricted in their survey. It is not enough to know the years of Galileo, of Harvey, or of Descartes, nor yet the particular contributions of Newton, Lavoisier, or Schleiden To these must be added the knowledge of the effects produced by these men and their works on the cultural state of the ages during which they lived. Copernicus did not merely reverse the gyrations of the sun and the earth; he shook the very firmaments, and dethroned man. Laplace did not merely formulate a dynamics of the universe, he deliberately and somewhat contemptuously excluded God from any part in the management of the universe. Darwin created an Aristotelian classification of living things, and advanced a Platonic hypothesis of progression which he termed organic evolution Darwin was guiltless of any rash or raw application of his theory of evolution to those phases of being which transcended his subject matter. But to his followers, numbered in millions, the struggle for existence and natural selection proved compelling ideas which discredited the ethical ideals preached by the Nazarene. Man, however, is not only a thinking creature, but also a spiritual, ethical being The foundation of civilisation is not figuratively the top layer of the human brain, his thinking mechanism, the pallium, but rather the underlying hypothalamus, the feeling centre Man's gregariousness made possible the instrumentalities of learning. Johnny Appleseed who planted so that those who came after him might reap, is symbolic of the best in man. Mutual aid, as Prince Kropotkin taught, and not the ruthless cut-throat competition of the deluded "realists," yielded all that is precious in civilisation. These deepest instincts of man have found expression in his professed ethics, and have been formulated in his religious confessions.

Modern science has taken little cognisance of the spiritual, ethical, and religious aspects of human existence Its measuring instruments have proved unsuited for the analytical study of man spiritual! Unable to grapple with the problem, science has argued away its existence; or being at times compelled by necessity, as when dealing with physiological psychology, to recognise the existence of "hope, faith, and charity," science has brought forth vapid mechanistic theories and equivalents of the soul.

There is, of course, no warrant for demanding that he who labours in search of the secrets, say of the viruses, shall also be competent to answer the riddle

of the human soul It will be well enough, as it seldom is, if the scientist sticks to his job and does not presume with his restricted competence to give judgment on matters outside his ken Unfortunately, the shoemaker does not always stick to his last The health educator must know not only the glories and achievements of modern science, but also its pretentions and limitations The health educator should know not only of the ecclesia's war upon science, but also of science's bitter war upon the ecclesia, which is understandable and to be forgiven, as well as of its war on religion, which may also be understood, but is harder to forgive

Finally, the health educator should not be without a knowledge of the great literature of the human race For otherwise he misses sharing in the most precious heritage of man

* * *

The cultural training of the health educator which I've sketched is not given as a curriculum for the novitiate It is not an absolute prerequisite to service It is a life time task, never to be completed But it is a desideratum, it is an obligation to the fulfilment of which we must devote our best years and energies

NURSES IN INDIA

THE Indian Nursing Statistics for 1937, compiled for the Trained Nurses' Association of India by Prof John Maclean, cover only British India, giving no information about the conditions of nursing in the native states In the 803 hospitals covered, with more than 20 beds each, there are 51,488 beds and 3259 trained and 3517 untrained nurses, as well as 565 male nurses The 1128 hospitals, with less than 20 beds each, have in all 14,195 beds and 743 trained and 53 untrained nurses, as well as 82 male nurses Unfortunately the returns from the different hospitals are made in a great variety of ways, some including male nurses in their totals, and some not doing so, for example. As a result, it is impossible from the figures given to draw any reliable inferences about the number of patients per nurse, the returns under this heading vary from 3 to 1460 The position is further complicated, as nursing help is, in many hospitals, given by relatives Prof Maclean is well aware of the deficits in these statistics, and has added a long list of corrections, together with a list of "entries suspect and requiring comment, if not correction" It is to be hoped that the necessity for more accurate returns will be borne in upon the numerous hospital authorities

On July 14, at a session of the Imperial Social Hygiene Conference, Miss D Hartley, secretary of the association, said that recently, without warning, an order had been issued in Madras cutting down the salaries of nurses by nearly half and stopping their special food allowances Further, in future male patients would be in charge of male nurses only This was affecting the recruitment of the best type of nurses in Madras

TO COUNTERACT ANXIETY

THIS little book [1] is written in a popular manner for the many who are feeling the effects of tension The writer has obviously had much experience of the thorny paths of neurosis, and his advice is drawn from what he has found most valuable in the teachings of the various schools of psychotherapy His division of the causes of acute anxiety into three—separation, guilt, and inferiority—is well conceived, and it may come as a surprise to patients, if not to their doctors, that their symptoms arise not from the political situation but from their own make-up Resentments are fully explained and helpful practical suggestions are made for their sublimation Whether, as seems to be suggested in the first chapter, discipline is sufficient to counter negative methods of thought is open to doubt, and the categorical statement that children cannot stand ridicule needs qualification The chapter which deals with religion and the open mind that welcomes the help it may give should be of value to a generation which represses the religious instinct

1 Fear and Depression Their Causes and Self Treatment. By a Medical Psychologist. Birmingham Cornish Bros 1939 Pp 90 5s.

A PORTRAIT OF REES

THERE are few portraits of George Owen Rees, whose activities as a pioneer in biochemistry were briefly described in our last issue, the British Museum apparently does not possess one A painting was made, however, by S Buck (not to be confused with the famous Samuel, who, with his brother Nathaniel, produced the well-known topographical series of engravings), and from it a mezzotint was made by Sydney Marks A copy, which has until recently been in the family of one of Rees's intimate colleborators, has reached the hands of Messrs Suckling and Co of London It is in perfect condition and bear Rees's autograph in pencil below the engraving "Truly yours, G Owen Rees"

LIMITATION OF OPIUM PRODUCTION

THE proposals of the advisory committee on the traffic in opium, dealing with the limitation of production of raw opium, have now been presented to the council of the League of Nations together with a draft of the articles which might be incorporated in a new convention Subject to certain reservations on behalf of some of the Powers there was general approval of the draft articles and, with some revision, these are to be submitted to the respective governments for their observations Thus Turkey welcomed the proposals, if convinced that the limitations proposed would effectually reduce illicit traffic and that all countries concerned were prepared to cooperate Yugoslavia, another producing country, wanted to be satisfied as to the crops which would replace poppy cultivation, and that the extraction of morphine from poppy stalks and capsules would be forbidden The Canadian representative was not satisfied with the information available in regard to opium production in Manchuria China, Afghanistan and Iran, nor as to the Persian monopoly of prepared opium, while the representative of China, disclaiming any responsibility for what is going on in provinces dominated by Japan, was prepared to achieve suppression of poppy cultivation in the area under Chinese jurisdiction not less rapidly than any other producing country

The principles which underlie the new draft convention are explained as being intended to supplement the provisions of the Hague Opium Convention of 1912 and of the Geneva conventions of 1925 and 1931 Production of raw opium is to be restricted to what is required (1) for medical and scientific purposes, (2) for manufacture of prepared opium pending its suppression and (3) for "other non medical forms of internal consumption" This last is presumably intended to meet the case of opium-eating as officially approved in India The amounts

of world requirements are to be arrived at by annual governmental estimates to be sanctioned and allocated by a controlling authority consisting of five members, the allocation to be either by quota or by a "free order system." Producing countries will undertake not to sow with poppy an area larger than will suffice to yield the allotted amount of raw opium, nor to export more than is assigned to them. Stock will have to be regulated and an adequate system of international control brought into operation.

The advisory committee has wisely requested the council to submit the draft proposals to a committee of jurists in order that they may "be put into proper legal form" and has nominated fifteen governments to appoint such jurists

ALCOHOL IN RELATION TO CRIME

FOLLOWING Dr. Norwood East's opening remarks at the discussion before the Society for the Study of Inebriety (reported on p. 136 of last issue) Dr. J. C. M. Matheson said he could confirm Dr. East's statement about the decrease in the number of female alcoholics received at Holloway Prison The daily average number of persons in custody convicted of drunkenness for the month of March, 1939, was, he said, 24 3 per cent. of the total prison population. I have, he continued, searched the histories of all the women received into Holloway Prison, charged with murder, since September, 1935, for a history of alcoholism with the following results Total number of prisoners received on a charge of murder—48. In no case where a conviction followed was alcohol found to be a factor. In 1 case the prisoner was reported to have frequented public houses with her lover but she was never reported to have been drunk, and the police considered her to have sober habits In 3 cases the habits of the women were irregular, 2 had been living rough, and 1 had been "on the streets," but there was no evidence that alcohol had played any part in the crime with which they were accused. In 1 case alcohol appeared to play a direct part. The victim was killed in a drunken brawl; at the trial the prosecution offered no evidence against the female accused, and she was found "not guilty."

RESERVES AND SUPPLIES OF FOOD

THE *British Medical Journal* last week offered suggestions for the home storage of food against a shortage in emergency. The British Medical Association (Tavistock Square, London, W.C.1) has issued these suggestions in a 2*d* booklet entitled "How to Stock Your A R.P. Larder." It shows the householder how best to act on the Government's advice that all who can do so should lay in a week's store of victuals

The larger question of supplies and storage are considered in "The Food Problem" by F. Le Gros Clark and R. M. Titmuss, issued in the Penguin series at 6*d*. This book will do a public service if it wakes the reader into a realisation of the need for organising the food-supply of this country not only for war but for peace. Mr Le Gros Clark discusses the relation of war and scarcity, the effect of blockade, home-farming and war, storage of food, the dispersal of stores and the future of the food trades. His conclusion is that sources of food and fuel are the weakest links in our chain of defence and that nothing but a sound policy of food storage, and control of such stores and policy by a representative food council, will make that link strong. The second portion of the book is concerned with stamina; and for this portion the two authors are jointly responsible. In spite of all the wastage of human life they see in our present organisation of society and the needless deterioration of stamina through insufficient and wrong food they conclude that "there is no basis whatsoever for pessimism or despair." They believe that with a sound food policy "we could be rearing a stock that would surprise the world by its vitality. So slight and so significant is the borderline between normal and subnormal humanity."

BLOOD-TRANSFUSION IN INFANCY

AN analysis has been made by E. Garcia Pérez of 4500 blood-transfusions given in three and a half years to children in the Hospital Municipal de Infancia, Havana (*Arch. Med. infant.* April–June, 1939, p. 106). That the tender age of a child is considered no bar to such treatment is shown by the fact that 107 transfusions were given to infants aged 1–30 days, 2183 to infants aged 1–12 months, and 1033 to those aged 1–2 years, making a total of 3323 to infants aged two years or less, as against only 1177 to older children up to twelve years. The remedy seems to be widely applied: toxæmia and convulsions were the indications for 2013 transfusions, and 176 were given for bronchopneumonia. The results in bronchopneumonia (acute non-tuberculous disease of the lung) are detailed by Agustin Castellanos and René Montero (*Ibid*, p. 116), who used 150–250 c.cm. of blood, obtained usually from a parent. No anticoagulant was employed, and the veins chosen were either the internal saphenous, external jugular, or antecubital. No reaction was observed and no accident happened. In the great majority of cases the fever, dyspnœa, and general symptoms abated. Cardiac insufficiency was not regarded as a contra-indication, but in its presence the preliminary withdrawal of a quantity of blood equal to that about to be injected is recommended.

In an analysis of 129 cases of infantile diarrhœa in infants aged two years or less, of whom 98 were given blood-transfusions, Cardelle Penichet, Hernández and Durán Castillo (*Ibid*, p. 138) report a case-mortality of 49 per cent. in those transfused and 42 per cent. in the others; but, in spite of these figures, they believe that *early* transfusion lowers the fatality. On the other hand, J. M. Smellie has pointed out (*Lancet*, 1938, 1, 1029) that these infants as a rule are not deficient in either erythrocytes or hæmoglobin, and holds that blood-transfusion is definitely undesirable except in those few who are proved to be anæmic Otherwise the addition to the total of erythrocytes merely throws an extra strain on the child. The need of transfusion to counter toxæmia has led to the giving of transfusions of blood-plasma alone.

A HUNDRED YEARS IN THE NURSERY.—Few remedies can have kept their place in the family medicine cupboard as firmly as Dinneford's Fluid Magnesia, which has lately celebrated its centenary. Its gentleness and palatability appealed to our forbears in their young days, and they appeal no less to our own children.

Medical Diary

July 24 to July 29

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane Road, W 12

WEDNESDAY.—NOON, clinical and pathological conference (medical) 3 P.M., clinical and pathological conference (surgical)

THURSDAY.—2.15 P.M., Dr Duncan White radiological demonstration

FRIDAY.—2 P.M., clinical and pathological conference (obstetrics and gynæcology)

Daily, 10 A.M. to 4 P.M., medical clinics, surgical clinics and operations, obstetrical and gynæcological clinics and operations

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, W.C.1

THURSDAY.—2 P.M., Dr W. W. Payne: The Uses of Oxygen in a Children's Hospital

MAIDA VALE HOSPITAL FOR NERVOUS DISEASES, W 9

THURSDAY.—3 P.M., Dr Russell Brain: clinical demonstration

EDINBURGH ROYAL INFIRMARY

THURSDAY.—5 P.M., Lieut.-Colonel A. G. McKendrick: The Dynamics of Crowd Infections (Honyman Gillespie lecture)

ADDRESSES AND ORIGINAL ARTICLES

FORTY YEARS OF PRACTICE

A RETROSPECT*

BY THOMAS FRASER, C.B.E., M.B., D.L.
CONSULTING PHYSICIAN TO ABERDEEN ROYAL INFIRMARY

IN pre-war days the most striking results from research in medicine were produced by brilliant individuals working with scant assistance, little money, and very limited time for nearly all had as their main jobs university teaching and/or honorary hospital appointments They invented their own apparatus and in many cases made it Of this class in our own University of Aberdeen were Ogston (whose mantle as president of the association, when it last met here in 1914, weighs heavily on my shoulders tonight), the discoverer, in the days of Lister, of the *Staphylococcus aureus*, which he used to describe in his quaint way as a "kindly little creature" compared with the virulent streptococcus, MacWilliam, the physiologist, whose classical work on cardiac muscle provided the foundation on which the brilliant clinical work of Mackenzie and Wenckebach was built, Hamilton, a great pioneer in pathology and bacteriology and a brilliant lecturer, Cash, pharmacologist of aconitine and arrow poisons

All were enthusiastic and able teachers of my student days and stimulators of capable youth to follow in their steps I shall mention only a few of those that readily occur to me in surgery Greig Smith, Scott Riddell, Marnoch, and Henry Gray, in physiology and biochemistry Leslie Mackenzie, Macleod (the initiator and head of the team which so brilliantly solved the insulin problem), Hugh MacLean, and Lawrence, in pathology and bacteriology Bulloch, Dean, and Ledingham, in pharmacology Cushny and Dilling

The output was small in those days as compared with the present, but the quality was usually very high Similar work was being done in such circumstances in many of the medical schools of the country In the post-war period both patient and practitioner alike—on many occasions simultaneously informed—are on many occasions simultaneously informed—of the most recent through the press, shall we say ?—of the most recent discovery, which is a source of embarrassment to the practitioner if he does not recognise that the latest knowledge is not always the latest truth In this period came a greater recognition by the state of the value of research, with a consequent outpouring of money on its behalf, and large sums were given by individuals to endow research and provide fellowships to support brilliant graduates for longer periods than was possible before

Research is no longer an individual affair as a rule, teamwork now prevails, and elaborate equipment, suitable accommodation, and skilled assistance are provided The output has increased and there is earlier publication of results, which has been one of the factors in increasing the number of specialists who can sift the facts of research and assess their applicability to the practice of medicine, and advise and instruct the general practitioner who calls for their assistance in his difficulties No doubt increased output and earlier publication have necessarily lowered the average of quality, but classical quality is still present—for example, insulin and probably the sulphonamide group

The British Medical Association's committee on nutrition has given much useful knowledge to practitioners and the public The pre-war practitioner can recognise the great improvement in the variety of food, and there is no doubt that nutrition has been in the limelight in post-war years, with considerable benefit as a result There is still lacking, however, in an important section of the population, a practical knowledge of food values and possibly a real knowledge of and interest in cooking This leads to a diminution in nutritive and reparative value and to the use of canned or bottled foods in increasing amount, even where fresh food is available at cheaper or at least more economic rates from the point of view of health and sustenance

* * *

There have recently appeared in our local press reports on the condition of the teeth of school children in country districts One education committee stated that less than a tenth of its school children had perfect teeth, and the only remedy suggested was the appointment of additional dentists In October, 1914, I took part in the examination of a county battalion of territorials from the same area, under immediate orders for France My colleagues and I noted that about 70 per cent of the men had excellent teeth, a finding which reveals a sad deterioration, in a quarter of a century, in a most important factor in healthy nutrition Yet there seems to be no need to despair, for I feel sure that the pre-war doctor, from his post-war experience, will agree that there has been great improvement in general health and that it is steadily progressive, with increasing momentum

This opinion is supported by the present Minister of Health, replying to a debate in the House last March, when he spoke as follows

"A great deal of action has been taken on the newer knowledge of nutrition, and there is a marked improvement in the health of the nation. This country consumes a large quantity of dairy produce If butter and cheese were counted as the equivalent of milk, the consumption of milk per head in this country has risen from 73 gallons in the five-year period 1925–29 to 89 gallons for the period 1930–34 This figure is higher than that in Italy, Germany, Belgium, France, and the U.S.A Butter, however, cannot be counted as simply the equivalent of milk; it ranks higher as one of the protective foods While poverty is a factor in the problem of nutrition it is also true to say that wages have risen and the cost of food has fallen"

He compared figures for 1927 and March, 1939, to show the improvements in the nutrition of the nation In 1927 the death rate due to infantile mortality was 70, maternal mortality 4·11, puerperal sepsis 1·57, and tuberculosis 79 Today the death rate due to infantile mortality is 55, maternal mortality 3·26, puerperal sepsis 0·98, and tuberculosis 56 Had he been speaking on the same subject today he would have been able to introduce rather telling support to the above argument from the reports of medical boards on the health and physique of the many thousands of militia in their twenty-first year recently called up for training One is ignorant whether and to what extent the standards previously applied to recruits for admission to the Regular Army have been modified, but even so, the published reports so far point to a great improvement in health and physique

Speaking in a debate on malnutrition in the House of Lords, Lord Hankey—who for nearly a generation,

* Abridged from the presidential address to the British Medical Association at Aberdeen on July 25.

as Sir Maurice Hankey, was secretary of the Committee of Imperial Defence—remarked that when he held that position he was profoundly shocked and humiliated by the fact that more than half the men offering themselves as recruits for the Army were rejected for physical and medical reasons He had been assured that the defects which caused the rejections were curable by proper nutrition, but that it took fifteen years to translate research into action. While public health had improved, much remained to be done. In the schools little was taught about nutrition, and what was taught was mostly out of date With the weight of the Government behind it there should be a sustained campaign or propaganda on the subject. One must keep in mind that the range of choice of recruits is now the widest possible socially, whereas in the days Lord Hankey refers to, apart from the war years, that range was very narrow. Indeed, in a considerable number of cases the stimulus to join the Army was often *faute de mieux*.

* * *

Food is not the only factor, though the most important, improved housing (including workshops), better sanitation; higher wages; shorter hours of work, giving more leisure, which is gradually being better spent; and greater opportunities for leading an open-air life—all are having their effect on the general health of the people To all this must be added the completely changed daily outlook of the industrial population, a considerable part of which in pre-war days, when unemployed from any cause, soon reached a state of threatening semi-starvation This change of outlook is due to workmen's compensation for accident, national health insurance, unemployment benefit, and other factors, all of which have had effects on our daily work as medical men.

The decline of emigration from this country is not entirely due to lack of opportunity to enter other countries; it results partly from a definite and widespread recognition of the opportunities offered here for a free and happy life despite the restrictions now being imposed by law and multiplied by the regulations, based on that law, which our bureaucracy determines. As supporting this opinion, one might point to the considerable number of men (and families) who returned to this country during the great slump of 1930 and following years, frankly recognising that life would be more tolerable here than in the United States and in parts of our Empire overseas under the prevailing conditions. Does the same view influence in some degree the gradually increasing number of distinguished oversea medical graduates who come to this country and often obtain high appointments? That we welcome them is evidence of our friendliness and hospitality, a matter which we trust will continue to be fully reciprocated in all parts of the Empire The Englishman—I omit the Scot on this occasion—has an astonishing sense of fair play, but to the observer he sometimes carries this to such a pitch that he ends by being unfair to himself, with somewhat disappointing results from the point of view of equity

* * *

In pre-war days it was by no means easy in these parts for the practitioner to persuade patients to enter our hospitals for observation and treatment This was greatly changed immediately after the war, and nearly all our hospitals have waiting-lists of such size as to be a menace to rapid improvement in health and restoration to full fitness of many on those lists. This menace is perhaps more apparent than real, for many of those waiting suffer from disabilities which do not interfere to a great extent with capacity for work, nor are they progressive. What was the increased attraction of the hospital due to? There was undoubtedly a great outpouring of war-accumulated wealth on charitable purposes, and voluntary hospitals benefited early and greatly from this, and as a result improved in their equipment and administration This, however, was a matter which took time to develop, whereas the snowball of influx to the wards and the outpatient department started almost immediately after the war, when beds were freed of men wounded or ill from troubles contracted on service. Being in general practice and also on the staff of the Royal Infirmary here, both before and after the war, I had an opportunity of observing this change from a somewhat unusual point of view, at least in a teaching hospital. I concluded that one of the most important factors in the early and rapid rise in the number of applicants for hospital treatment was the fact that enormous numbers of men and women who under peace-time conditions would have been treated in their homes were during the war treated in hospital. A good many millions were removed from their homes on war service, both at home and abroad When they were wounded or ill, attendance and treatment were a matter of concern to the state and to employers, because their speedy restoration to health seemed more important than ever before, and controlled treatment, such as can best be provided in hospital, became the rule. On the return of these patients to civil life these benefits were not forgotten, and it was apparent that the treatment that could be provided in their homes for certain maladies was unfavourable compared with what they had received during the war for similar types of illness; so not only was there a much readier acceptance of hospital treatment when recommended but also it was very often asked for when there was no real need. This was one of the earliest factors to remove from the minds of many the curious idea that the hospital was a place in which to die rather than to recover.

* * *

All this led to a clamant need for the extension of hospital accommodation. In Aberdeen it was recognised early after the war; but many difficulties had to be overcome before our hospitals reached the capacity they now have The idea of our joint hospital scheme originated in the brain of the late Prof. Matthew Hay, medical officer of health for the city, and was first declared in our Medico-Chirurgical Society (which this year celebrates the 150th anniversary of its foundation) in the year of the presidentship of the late Sir Ashley Mackintosh, an ardent supporter of the scheme A committee was formed with the medical officer of health as an active and inspiring member The first check came when Professor Hay's successor as M.O.H declined the committee's invitation to join them. It was decided that to ensure success in the raising of the money it was essential that the leading citizen, the Lord Provost, should take a prime interest in the scheme. In the face of lukewarmness, to say the least of it, on the part of the public-health committee of the town council, and owing to the fact that provosts reign for at least three years, it was not until 1927 that Mr (now Sir) Andrew Lewis agreed in the second year of his office to raise the necessary funds, provided that the scheme had the hearty support of the medical profession Sir Andrew no doubt acted on his knowledge of the corporation's intention to convert the

poor law hospital into a large municipal general hospital

Two meetings of the Medico Chirurgical Society were held, at both of which I was accidentally in the chair The first took place in a somewhat electric atmosphere, in which much prolonged and contentious argument ensued revealing more opposition to the scheme than had been expected The debate lasted almost to midnight, when the meeting was adjourned for a fortnight and then resumed in a calmer atmosphere The tempers had by then cooled, and the vote in favour of the scheme was such that Sir Andrew at once took it up With uncommon wizardry, in two years he collected over £400,000, a very large proportion being raised from the area which the hospital serves and which has a population of about 300,000—a fine achievement Two future kings were associated with the undertaking King Edward VIII, when Prince of Wales, laid the foundation stone in 1923 and our present King, as Duke of York, opened the hospital in 1936 As the hospital neared completion it was found that £100,000 more would be required to free the building fund from debt, and again it was fortunate that the stern occasion produced the man Lord Provost Watt undertook what was recognised as a very difficult task after the way in which the area had already been drained Such were his energy and enthusiasm that in one year he found the money, and his is one of the names which should be placed high in the infirmary's roll of service

* * *

This year the British Medical Association holds its 107th annual meeting The number alone indicates persistent continuity in time, and those who know its history recognise a continuity in purpose and in progressive achievement—a tribute to the vision of those provincial men in Worcester who founded this association in 1832 It is now holding its annual meeting for the second time in this historic city, at its highest peak not only in membership but in influence with the community and the state, its area Empire-wide, and its public spirit second to that of no other similar body In 1914, when the meeting was last held here, its membership was about 22,000, now it is 38,000 A considerable part of my leisure during forty one years of practice has been occupied in the work of the association, and it has been a great privilege and an honour to serve it in various capacities during that time It is true that the quality of that service has varied owing to the restrictions which irregular demands on his time impose on the general practitioner, particularly if in charge of medical wards and engaged in clinical teaching, but the service has always been interested, making the advancement of the association its chief aim

* * *

Those who practised medicine at the beginning of this century had few evidences of state control such as exists now Death, lunacy, and vaccination certificates were a state matter, and, later, notification of certain infectious diseases, for which nominal fees were paid, was a municipal matter, but these were the main contacts of the practitioner with the state and the municipality at that time No striking change came until that stormy petrel of politics, Mr Lloyd George, then chancellor of the exchequer, appeared on the medical horizon with his national health insurance proposals and the profession saw itself threatened with a form of control entirely foreign to all its traditions In the days before the National Health Insurance Act the usual method of starting practice in Aberdeen was to put up a plate and wait for patients To the young practitioner election as medical officer of a society was a boon, it gave him work on which to build up a reputation and enlarge his experience The disadvantages, however, were many, among them undignified competition for such posts and no security of tenure The proposed act removed many of these disadvantages but promised others of unknown effect

* * *

In 1931 another event occurred in which the altruism of the profession in regard to state and community was again to be demonstrated, and on this occasion it did not fail to impress the Government of the day This was the attitude of panel practitioners to the proposed salary cuts at the time of the great slump To the extent of their panel fees panel practitioners were to be considered Government servants These fees were not salary in the ordinary sense but capitation fees which included all out-of-pocket expenses incurred in attending panel patients Headquarters were assured by the then Minister of Health that the Cabinet had decided that a 10 per cent cut on all salaries paid by the state was to be made, and that this cut would be imposed centrally The British Medical Association through its Insurance Acts Committee held a conference in London of panel practitioners, members and non members alike, representative of all parts of the country, and after a prolonged debate it was decided, with few dissentients, to accept the proposed course on the assurance given Parliament, however, did not accept the Cabinet's recommendation The amount of the cut was not fixed at 10 per cent all round nor was it to be imposed centrally in all cases In many it was left to local authorities to decide the amount of the cut, and in this town some escaped altogether, others had 2½, 5, and 7½ per cent deducted, on a few only was the 10 per cent imposed All panel doctors, however, bore a deduction of 10 per cent from their fees for attendance on insured patients, and it was imposed centrally Though there was much argument and much conferring with the Ministry of Health, it was ultimately accepted as a contribution to the National Exchequer in a time of emergency

* * *

From its foundation in 1832 the British Medical Association has been chiefly concerned with (1) the maintenance of the professional standard of education and conduct (both pre and post graduate), (2) promotion of scientific research, (3) promotion of a national public health policy which will allow the profession to make its maximal contribution to the well-being of the country, and (4) improvement of efficiency in all branches of medical practice at home and abroad Its work and attainment since 1925 show it to be an increasingly effective force in the promotion of the common health, not only in this country but overseas as well The first Medical Act of 1858 was based upon a bill drafted by the association, and therefore the association can claim to have been largely instrumental in establishing the General Medical Council

Promotion of scientific research was instituted in 1900, when there was great need of assistance in this regard on account of lack of funds for medical research both in universities and in hospitals Committees have submitted reports on matters connected with the

promotion of health, and many of these have been taken up by the Government and incorporated in acts of Parliament, such as the Medical Inspection of School-children Act A similar report was issued in 1909 regarding ophthalmia neonatorum, and compulsory notification was strongly urged in that report This was adopted by the Government in 1914 A long list of similar events could readily be given, but I will mention only one, which was possibly unique because the association on that occasion was asked by the Government to present a report on physical education Our great association, with its Empire-wide connexions and influence, has in the past played a notable part in the promotion of health, and one feels confident that so long as it continues to attract to its council men of knowledge, public spirit, wisdom, and vision, its accomplishment in that direction in the future will transcend all its past achievement.

ACUTE HYPERPARATHYROIDISM

By W A Oliver, M D Lond, M R C.P.
SENIOR DEMONSTRATOR OF MORBID ANATOMY AND HISTOLOGY AT ST BARTHOLOMEW'S HOSPITAL, LONDON

The possibility that the findings in dogs subjected to an experimental overdosage of parathyroid hormone might be reproduced in man has been recognised for some time, but only three cases, of which one alone was fully proven, have been published.

Dawson and Struthers (1923) describe the case of a man, aged 49, with a long history of the typical bone lesions of hyperparathyroidism with multiple fractures, who, while under observation, had an acute syncopal attack and was admitted with collapse and a rapid feeble pulse to hospital where he died soon after admission. Autopsy showed a parathyroid tumour and extensive generalised calcification in the vessels, heart, lungs, stomach, kidneys, spleen, and liver.

Lowenburg and Ginsburg (1932) describe the case of a boy, aged 5, who, in error, received 100 units of parathyroid hormone daily for six days; on the second day of this treatment he began to vomit and became listless; by the fourth day mental depression had become extreme, he did not respond to even strong stimuli, and high irregular fever with tachycardia was present.

On the sixth day the error was discovered and a blood examination showed serum calcium 19 6 mg. and phosphorus 4·4 mg. per 100 c.cm. When the administration of parathyroid hormone was stopped, the blood chemistry and the clinical condition rapidly returned to normal.

The only case which has been fully proven is that described by Hanes (1939). A woman, aged 49, who had previously been in hospital with pyelitis, was admitted because of increasing weakness, pain in the chest, and much loss of weight. Previously a radiogram of her kidney had shown diffuse fine mottling, examination of the serum calcium had given a figure of 12 mg. per 100 c.cm., and renal function tests had shown considerable impairment.

On examination at her last admission, five years later, a tumour was palpated at the lower pole of the thyroid, radiography showed decalcification of the bones and what was now recognised as the changes typical of metastatic calcification in the kidneys Blood examination showed calcium 20 rising to 22 mg per 100 c cm, phosphorus 4 7 mg. per 100 c.cm., phosphatase 23 Bodansky units, and non-protein nitrogen 58 mg. per 100 c cm. Renal function tests showed severe impairment

While awaiting operation, the patient became increasingly weak and mentally depressed, developed fever and tachycardia, complained of generalised aching pains, and died before operation could be carried out.

Post-mortem examination showed a necrotic and partially calcified parathyroid tumour, composed of chief cells, and diffuse visceral and vascular calcification. The lesions in the kidney, though widespread, were considered to be insufficient to cause death

In view of the apparent rarity of this important and curable condition, the following two cases are placed on record

CASE-RECORDS

Case 1.—A woman, aged 57, was admitted to hospital on Jan 3, 1939, complaining of nausea and retching, loss of weight, weakness, and drowsiness Her drowsy condition made it difficult to obtain her history, and it was necessary to obtain all details from a relation.

For six months she had complained of increasing loss of strength and had lost 1 st. in weight; for two weeks there had been almost complete anorexia with much nausea and retching on any attempt to take solid food; constipation was obstinate, there was no hiccough; and during the two days before her admission she had become progressively more drowsy and unable to keep her eyes open.

Her past history showed that constipation had increased recently, and that she had had occasional attacks of dyspnœa and œdema of the ankles, her memory and mentality had remained normal up to the time of her present illness, there was no past history of renal disease; and she had not taken any depressant drugs.

On examination she was very drowsy but could just be roused. Her temperature was 97° F., pulse-rate 88, and respiration-rate 15. The central nervous system was normal, apart from increased briskness of the reflexes on the right side. The tongue was dry and brown The lungs were normal, apart from emphysema. The heart was not enlarged, the pulse was regular, and the blood-pressure was 160/100. The left kidney was palpable and tender.

Examination of two different catheter specimens of urine showed specific gravities of 1 010 and 1 005 albumin, occasional red blood-cells and granular casts, and numerous white blood-cells and hyaline casts. The urine was sterile on culture The daily excretion of urine averaged 1000 c cm, with an average intake of 1400 c.cm. until she became incontinent, making accurate measurement impossible.

Lumbar puncture yielded a normal cerebrospinal fluid, apart from a raised chloride content of 800 mg. per 100 c.cm. Two estimations of the blood-urea, two days and eight days after admission, showed respectively 76 and 136 mg per 100 c cm., the alkali reserve on the latter occasion being 75 8 c cm of CO_2 per 100 c cm. of plasma.

Progress —The patient became increasingly stuporose, with a progressive fall in blood-pressure to a final reading of 70/50 on the day before death. The tongue and skin remained very dry; there was a terminal rise of temperature, pulse-rate, and respiration-rate; and the patient died nine days after admission without ever developing any localising physical signs.

Post-mortem findings —Brain: a small meningioma was found in the right anterior fossa. Parathyroids: beneath the right inferior lobe of the thyroid was a brownish-yellow tumour measuring 3 8 by 1 8 cm. in its longest diameters and weighing 3·8 g. (fig. 1). Heart: muscle soft and fatty, otherwise macroscopically normal. Kidneys: cut surface showed numerous small calcareous flecks, but no other macroscopic change Bones: no evidence of decalcification or cyst formation. The remaining organs were macroscopically normal. The blood calcium was 17 4 mg. per 100 c.cm and the urea in the cerebrospinal fluid 110 mg per 100 c cm

Histology. — *Parathyroid tumour*; chief-cell adenoma, no oxyphil cells present. Heart: wide-

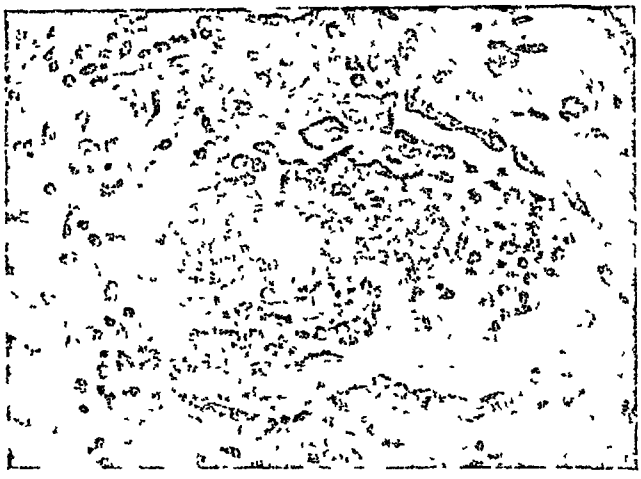

FIG. 3—A glomerulus in case 2, showing necrosis, deposition of calcium, and foreign-body giant-cell reaction (× 340)

and the vessels Thyroid · no deposition of calcium Voluntary muscle. no evidence of medial hypertrophy in the vessels. Spleen and liver: normal, apart from some hyaline thickening of the intima of the vessels, especially in the spleen, and excessive deposition of calcium in the internal elastic lamina

Summary of post-mortem findings.—Chief-cell adenoma of the left inferior parathyroid, with widespread necrosis and deposition of calcium in kidneys, lung, heart, and stomach, and in the vessels in nearly all the organs.

DISCUSSION

Cause of death.—In the absence of more complete investigations, omitted because the diagnosis was not suspected before autopsy, it may be argued that there is no clear evidence that death was due to acute hyperparathyroidism. However, review of the post-mortem findings, both macroscopic and microscopic, shows that, apart from the parathyroid adenomata and the necrosis with associated deposition of calcium, the organs were essentially normal, and that nowhere else was there any lesion sufficient to cause death As positive evidence, there may be adduced the facts that there was in each case a parathyroid adenoma, with the well-recognised pathological syndrome of widespread deposition of calcium and a very high value for the serum calcium (as a control, ten post-mortem estimations of serum calcium, taken at random both as regards age and time after death, have given essentially normal results) In case 1 none of the organs showed sufficient pathological change to cause death as a result of failure in function of that organ alone, the changes in kidney and heart, though widespread, were not severe and do not appear to have affected in any way their functional capacity

In case 2 fairly severe lesions were found in the kidney, and, in view of the raised blood-urea during life, it cannot be stated dogmatically that uræmia was not the immediate cause of death. The clinical features, however, did not closely resemble those of uræmia, for there were no neurological manifestations, no hiccough, no diarrhœa no evidence of acidosis, and no œdema; the blood-pressure was not raised, there was no cardiac enlargement and no severe degree of anæmia, the urea in the cerebrospinal fluid post mortem was only 60 mg. per 100 c.cm (the rather high figure of 176 mg. found in life was possibly due mainly to the severe dehydration after vomiting) The lesions in the heart, although widespread, did not appear sufficient to cause death. It therefore seems reasonable to suppose that death was due directly to the results of an acute hyperparathyroidism

Various theories as to the exact mechanism of death, both in the experimental overdosage with parathyroid hormone and in the human cases reported, have been postulated. Hueper (1937) has suggested that symptoms are caused in experimental animals by an exaggeration of the normal physiological tonic effect of parathyroid hormone, death being due to cessation of the heart in systole. Hanes (1939) considered that death had resulted in his case either from myocardial failure, due to the severe myocardial lesions, or that it had been a "chemical" phenomenon, lack of diffusible phosphorus in the presence of a very high serum calcium being the explanation. The exact mechanism of this latter hypothesis was not discussed Recent experiments of Shelling et al (1938) have again suggested a chemical mechanism, they postulate that the parathyroid may play a considerable part in the distribution of water and electrolytes, other than calcium and phosphorus, and that death, in their animals, after an overdose of parathyroid hormone was due to the loss from the body of fluid and electrolytes; he was able to prevent symptoms by continuous supply of fluids and electrolytes In the cases under discussion it is certain that death was not due to the kidney lesion, there being large numbers of normally functioning glomeruli still present in both cases The severity of the cardiac lesions in case 2 and the tachycardia out of proportion to the fever in both cases support Hanes's view, but the minimal histological changes found in the myocardium in case 1, who died an exactly similar death, appear to negative that suggestion What part dehydration and loss of electrolytes played in these cases it is impossible to say on account of inadequate investigation, but a combination of this factor with failure of the brain to utilise glucose in the absence of diffusible phosphorus is at least a possible explanation of the gradual

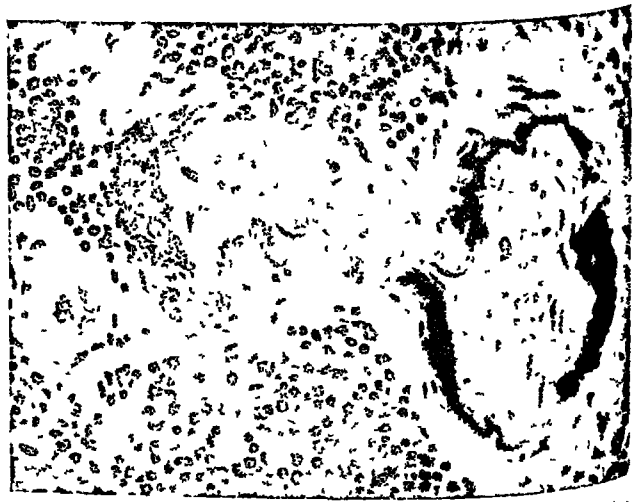

FIG 4—Interlobular vessels in the kidney of case 2 Hyaline thickening of the intima and deposition of calcium in the internal elastic lamina can be seen (× 325.)

onset of coma—i.e., death in each case was "biochemical"

Symptoms.—The similarity between the clinical features of the two cases is very marked. Symptoms were present for an approximately similar time before admission, and the prominent symptoms were repeated nausea and vomiting, anorexia, much loss of weight, obstinate constipation, and, terminally, rapidly increasing drowsiness. In both cases examination showed severe dehydration, an irregular pyrexia with tachycardia out of proportion to the slight fever, no cardiac enlargement, a low blood pressure, and no other significant physical signs. Laboratory examination in each case showed a slight hypochromic anæmia and evidence of renal damage but no significant change in the alkali reserve. The terminal course in each case was similar, with rapidly increasing stupor and a progressively failing blood pressure (final readings: case 1, 70/80; case 2, 104/86).

SYMPTOMS OF ACUTE HYPERPARATHYROIDISM

Case	Vomiting and anorexia	Loss of weight	Asthenia	Constipation	Mental retardation	Pain in the chest
Case 1	+ +	+ +	+ +	+	+ +	−
Case 2	+ +	+ +	+	+ +	+ +	+ +
Lowenburg and Ginsburg (1932)	+ +	No rec.	+	No rec.	+ +	−
Hanes (1939)	No rec.	+ +	+		+	+

rec. = record.

A comparison with the clinical features and findings of two of the previously reported cases (Lowenburg and Ginsburg 1932, Hanes 1939) shows many points of similarity (see table). In none of the cases was there clinical evidence of hypertension, though all the three proven cases showed definite evidence of impaired renal function.

The case reported by Schrumpf and Harbitz (1937), although post mortem proof is lacking, appears to have exhibited very similar though less severe clinical features.

A man, aged 54, complained of lassitude, pain in the back and legs, weakness, and disorientation. Examination showed typical mottling of the kidneys, a tumour in the neck, absence of decalcification of bones, impaired renal function, and a serum calcium of 20 mg. per 100 c.cm. At operation two parathyroid chief cell adenomata were removed, with consequent complete relief of symptoms, although evidence of impaired renal function persisted.

Albright, Aub, and Bauer (1934) consider the symptoms (hypotonia, lassitude, constipation, and loss of appetite with resulting loss of weight) as being typical of hyperparathyroidism but postulate hypertypical of hyperparathyroidism but postulate hypercalcæmia as the immediate cause. It thus appears that the symptoms associated with an increase of circulating parathyroid hormone constitute a fairly well defined syndrome, and that, if a patient exhibiting these general symptoms becomes drowsy and develops fever and a tachycardia out of proportion to the fever, the immediate prognosis is serious.

The symptoms in experimental overdosage of parathyroid hormone in dogs, although not strictly comparable, are in many ways strikingly similar. Collip (1926), Hueper (1927), and Cantarow et al. (1938) report weakness, vomiting, anorexia, and rapidly increasing mental depression, with death in coma, as being typical of the experimental syndrome.

Morbid anatomy.—The exact significance of the pathological changes found in the two cases is difficult to assess, because it was not possible to fix the organs immediately after death, it is, however, clear that the morbid changes in each case are widespread and essentially similar. In case 2 the lesions in general are much more severe than in case 1.

The finding of parathyroid tumours, composed of chief cells only, indicates a definite adenoma secreting parathyroid hormone, as distinct from the general hyperplasia of the parathyroids, seen so often in chronic renal disease or the large oxyphil adenomata which may be found without any symptoms or change in the serum calcium (Hadfield and Rogers 1932).

Glomerular necrosis with only minimal deposition of calcium suggests that the necrosis may have been the primary change, providing a particularly suitable soil for secondary deposition of calcium. Post-mortem degeneration made tubular necrosis difficult to assess, but calcification in the tubular epithelium did not occur without necrosis. Hypercalcæmia alone, as seen in experimental hypervitaminosis D, produces calcified lesions in the kidney which are quite different, large amounts of calcium blocking the normal tubules, the glomerular changes being minimal, and considerable amounts of calcium being deposited in the interstitial tissue. The tubular lesions somewhat resemble those due to poisoning with corrosive sublimate, in which calcium is deposited in the necrosed convoluted tubules. In neither of these patients was there any possibility of this being an etiological factor, but the production of closely similar tubular lesions by a known necrotising agent is noteworthy.

The cardiac lesions were severe in case 2 and comparatively mild in case 1 but were essentially similar and consisted of destruction of muscle fibres with deposition therein of calcium. Convincing evidence of necrosis without calcification is absent, although in case 2 one probable such area was seen. The arterial change was similar to that seen in the interlobular vessels of the kidney (fig. 4).

The deposition of calcium in the stomach and lungs was not associated with necrosis. In any condition of hypercalcæmia, however, calcium is deposited in these sites irrespective of previous cell damage on account of relative cell alkalinity resulting from acid secretions.

The arterial lesions seen in the kidney, heart, spleen, liver, and many other organs as well as in the femoral and other larger arteries, consisted of deposition of calcium in an already damaged vessel. In the absence of any evidence of arteriosclerosis or atheroma it is suggested that the degenerative lesions seen are the primary result of the toxic action of excess circulating parathyroid hormone, and that the calcification is secondary to this change.

The lesions found in these cases appear to correspond closely with those previously reported (Dawson and Struthers 1923, Hanes 1939). Hanes emphasises "injury necrosis" as the essential lesion; from the ambiguity of the term it is not clear whether in his case necrosis was the primary lesion or secondary to injury from deposited calcium. Albright, Baird, Cope, and Bloomberg (1934) recognise three types of renal lesion in hyperparathyroidism: type I, stones with pyelonephritis; type II, calcium precipitates in the tubules with chronic kidney damage; and type III, 'acute parathyroid poisoning with anuria and death from undetermined cause in a few days, with calcium deposits in the kidneys and in other organs, but with no chronic renal changes.' They

had not seen a case of type III The cases herein reported appear to belong to this category. Careful study of the histological changes in experimental parathyroid hormone overdosage in rats and dogs (McJunkin et al. 1932, Cantarow et al 1938) indicate that necrosis always precedes calcification Although the kidney lesions, especially in case 2, closely resemble those in Cantarow's dogs, they are not strictly comparable, on account of the delayed fixation. No specific mention of arterial lesions, apart from calcification, is made, and an experimental proof of the hypothesis that overdose of parathyroid hormone can cause arterial degeneration is being attempted. Other experimental changes reported by Cantarow, such as focal fatty degeneration of the liver and hæmorrhages into the splenic follicles, were not seen in the cases under consideration.

That the pathological lesions are not simply the result of hypercalcæmia seems probable McJunkin was able to produce comparable lesions only after prolonged intraperitoneal injections of calcium gluconate and considers that direct toxic action of parathyroid hormone on the cells probably plays an important part (McJunkin et al 1932) During the experiment one of Cantarow's dogs delivered herself of a litter, in which, although a hypercalcæmia, comparable with that of the mother, was found, no necrosis or calcification in the organs was present, suggesting that the necrotic lesions seen in the mother were the result of excess parathyroid hormone and not of the hypercalcæmia (Cantarow et al 1938). In hypervitaminosis D, although there is persistent hypercalcæmia, the lesions produced, especially those in the kidney, are not like those produced in experimental overdosage of parathyroid hormone or like those produced in these two cases. An arterial degeneration, however, apparently similar to that observed, is sometimes seen in the experimental condition (Kleitmair and Moll 1928), and it may well be that the arterial lesion in these cases is merely the result of hypercalcæmia

CONCLUSION

Whatever the exact significance of the pathological changes or the mechanism of the mode of death, it is clear that these cases represent an important clinical syndrome, which it should be possible to recognise before death A clinical picture including vomiting, loss of weight, anorexia, bone pains, constipation, and lassitude, all of them recently exacerbated, with increasing drowsiness, and evidence of fever, disproportionate tachycardia, and impaired renal function without hypertension, should prompt a careful examination of the neck for a parathyroid tumour, estimation of the serum calcium and phosphorus, and radiography of the kidneys From the experiments of Shelling et al. (1938) and the clinical reports of others (Lowenburg and Ginsburg 1932, Schrumpf and Harbitz 1937–38) it appears clear that the ill effects may be reversible, and that, if suitable fluid and electrolyte replacement is carried out and followed by removal of the tumour, good results may be expected, therefore recognition of the condition and its speedy confirmation by investigation are of considerable importance.

SUMMARY

(1) Two cases of parathyroid chief-cell adenomata associated with widespread deposition of calcium are described. (2) The clinical features and histological findings are reviewed and compared with experimental lesions (3) The suggestion is made that the cases constitute examples of a clinical syndrome—acute hyperparathyroidism—which, if recognised, is amenable to therapy.

My thanks are due to Dr. A. E. Gow and Dr. G. Evans, physicians to the hospital, for permission to publish these cases; to Prof. G. Hadfield, pathologist to the hospital, for helpful advice and criticism; and to Miss Peiser, photographic technician, for the photomicrographs.

THE EFFECT OF SULPHONAMIDES ON BLOOD-SERUM

BY G. ALLAN SCOTT, M.B Edin, M.R.C.P.E
CLINICAL ASSISTANT AT THE SUTTON AND CHEAM HOSPITAL, SUTTON, AND
O. MEERAPFEL, M.R.C.S.
LATE SENIOR RESIDENT MEDICAL OFFICER AT THE HOSPITAL

DURING the last few months we have been presented with a new problem by two cases under treatment with sulphonamide drugs. The phenomenon, we feel, is worth recording, even with so few cases, to invite observation and comment from others with more clinical material at their disposal.

CASE-RECORDS

CASE 1.—A boy, aged 14, was admitted on Nov. 2, 1938, with a history of an insect bite over the right hand a fortnight previously, followed by a whitlow on the same hand, a whitlow on a toe, and boils on the chest wall. During the next week he had shivering attacks, felt very weak, and developed a dull pain in the left hip. Two days before admission he developed a sore throat and a tight feeling behind the sternum.

On *admission* he was very weak and unable to move, he was flushed with circumoral pallor, and his skin was clammy. Temperature 103·4° F., pulse rate 120, respiration-rate 28. Respiration was rather laboured, with active alæ nasi. Some moist crepitations over the bases of both lungs Nothing abnormal was detected in heart, abdomen, or central nervous system. Local lesions included a healing septic spot over the back of the right hand, an extensive whitlow on the right little finger, a whitlow on the left big toe, and boils on the chest wall. The left hip was extremely tender on pressure anterior to the joint and over the greater trochanter; the movements were too painful to be tested.

On the 5th jaundice set in and was rapidly deepening. The liver was not palpable, and the band of liver dullness was very narrow. No leucine or tyrosine was found in the urine. A blood-count gave the following results —

Red cells	1,200,000	Polymorphs	85%
White cells	18,200	Lymphocytes	11%
Hæmoglobin	70%	Monocytes	4%

The blood belonged to group A, and the patient's father was compatible as donor. Blood-culture

produced a pure growth of *Staphylococcus aureus* Treatment was started with Ulcron (Bayer) gr 7½ four-hourly

On the 10th the temperature was settling and the jaundice disappearing The patient was extremely pale and weak Blood transfusion (drip method, 350 c cm. given over three hours) was followed by a severe reaction with several rigors and pyrexia up to 106 4° F Cross-grouping now showed a slight agglutination of the father's cells by the patient's serum

On the 12th a slight pericardial rub was detected On the 25th it was found that a large pericardial effusion had developed during the last few days The pericardium was tapped and 150 c cm of a cloudy yellow fluid removed, which contained 13,600 cells per c mm , being 05 per cent polymorphonuclear and 5 per cent endothelial cells A few red cells and cocci were also seen Culture produced a pure growth of *Staph aureus*

On Feb 27, 1939, it was noted that during the last three months several more joints had been involved in a purulent arthritis, but most of them had cleared up under treatment by extension immobilisation, and other methods, and ulcron had been given until today in the above-mentioned doses over ten days at a time with intervals of five days Temperature and pulse-rate had now been normal for some time, the heart dullness was normal, and the sounds were clear The left hip was ankylosed, and the left knee and ankle were completely disorganised and showed chronic suppuration The right knee and ankle and the left elbow, which had also been involved, were clear During this time the anæmia had not increased very much, but a further blood-transfusion had been thought to be helpful Six donors of the patient's own group (A) and two universal donors were tested, but all were incompatible The patient's cells showed all the time a clear group-A reaction

On April 11 the patient's left leg was amputated after a blood-transfusion (drip method, 500 c cm over three hours) The first donor tested (group A) was compatible This was twelve days after the last dose of ulcron

On May 31 the patient was still in hospital but convalescent and making good progress

The total amount of ulcron administered was gr 423 gr 36 in six consecutive days before the blood-transfusion on Nov 11, gr 366 between the first blood-transfusion and the second (given on April 11), and gr 21 in the next week

CASE 2.—A girl, aged 6, admitted on Dec 27, 1938, with a history of two days' fretfulness and refusal of food except fluids There was a vague pain in the left lower part of the abdomen Bowels and micturition were normal

On *admission* she had a dry tongue and a flushed and clammy skin Temperature 100 2° F., pulse-rate 120, respiration rate 24 There was some vague aching on movement of the left leg Otherwise physical and laboratory examination did not show any abnormalities

On Jan 3, 1939, the temperature suddenly rose to 101° F , the pulse-rate being 140 and the respiration-rate 36 A scarlatiniform rash developed over the forehead and spread rapidly over the rest of the body No other abnormal symptoms or physical signs were detected A blood-count gave the following results —

Red cells	3,000,000	Polymorphs	91 5%
White cells	55,400	Lymphocytes	4 5%
Hæmoglobin	70%	Monocytes	1 0%

There was a considerable "shift to the left" A blood-culture proved sterile Treatment with sulphanilamide gr 3½ four hourly was begun

On the 7th the rash had disappeared and temperature, pulse rate, and respiration rate were normal

On March 14 it was noted that such attacks of rashes combined with pyrexia had recurred three times, always without other physical signs and always quickly controlled with sulphanilamide The blood-picture always suggested suppuration, but no focus had been found. Radiography of the chest and joints and examination of urine, stools, and throat swabs had given negative results Blood-culture proved sterile on five more occasions A blood-count gave the following results —

Red cells	4,400,000	Polymorphs	81%
White cells	64 000	Lymphocytes	18%
Hæmoglobin	70%	Monocytes	1%

On the 18th a similar but more severe attack came on which lasted eight days On the 20th and 22nd blood cultures produced pure growths of hæmolytic streptococci Sulphanilamide was increased to gr 7½ six-hourly on the 20th The patient became weak and pale, and a blood-transfusion (drip method, 300 c cm) was given on the 23rd This was on the fifth day of treatment with sulphanilamide and the third after the dose had been increased There were no complications

On April 20 it was noted that there had been three more attacks but much less severe The patient was on sulphanilamide all the time, but no more blood-cultures had produced growths The patient had become anæmic again, and a further blood transfusion had been contemplated The patient's serum, however, had been found to agglutinate the cells of five donors tested, all being of her own group (group O) On the last occasion the serum of the patient had agglutinated her own cells after they had been washed in citrated saline solution By now the patient had become extremely pale Agranulocytosis (no sore-throat) was found for the first time A blood-count gave the following results —

Red cells	1,100,000	Polymorphs	3%
White cells	64 000	Lymphocytes	66%
Hæmoglobin	no estimation possible	Monocytes	31%

1 myeloblast, 1 normoblast, severe polychromasia and anisocytosis

Sulphanilamide was stopped, and the patient was given large doses of iron and occasionally liver extract by mouth Other treatment for the agranulocytosis was not given, for the excitement of undergoing injections was considered more than the patient could stand at this stage

On the 28th there had been no more attacks A blood-count showed hæmoglobin 25 per cent , 1,700,000 red cells, and 20,000 white cells, of which 30 per cent were polymorphonuclears Blood-grouping with a donor previously found incompatible showed perfect matching No further transfusion was given

On May 17 a blood-count showed hæmoglobin 80 per cent and 4,300,000 red cells

On the 31st the patient was well and putting on weight, the blood picture being normal She has just left hospital for a convalescent home

The total amount of sulphanilamide administered was gr 718 gr 170 during the early stages of the disease, gr 120 in five days before blood transfusion (followed by an interval of twenty days), and gr 428 thenceforth until agranulocytosis was detected

EXPERIMENTS

Struck by the similarity of these two cases with regard to blood-grouping, we tested the serum of six other patients under treatment with different sulphonamides for various conditions, such as local sepsis, pneumonia, and quinsy The patients were all adults and on comparatively smaller doses than were the above mentioned patients None of them gave any abnormal results as regards grouping and cross-grouping of their blood with corresponding donors

We next investigated the action of these drugs in vitro and as a result we found that normal serum treated for some considerable time (four days and

more) with (in our case) sulphanilamide in a concentration of about 2½ per cent appears to agglutinate any cells tested—i.e., cells derived from donors of the corresponding group or from universal donors

SUMMARY

(1) Two cases are described in which treatment with a sulphonamide over a long period and in large doses (uleron gr. 423 in one case and sulphanilamide gr. 748 in the other) was followed by an alteration in the blood-serum which precluded the finding of a suitable donor for blood-transfusion

(2) Normal serum treated in vitro with sulphanilamide for four days or more agglutinated the red blood-cells of donors of the corresponding blood-group and the cells of universal donors.

(3) When these drugs were administered over shorter periods and in smaller doses to six other patients such a change in the blood-serum did not take place

Our thanks are due to Dr. C. Carron Brown and Mr T. E. Stoker for permission to publish these cases.

A CASE OF CHLOROMA

BY IDRIS G. JONES M.D. Lond., M.R.C.P.
ASSISTANT REGISTRAR AT THE NATIONAL HOSPITAL, QUEEN SQUARE

THE rarity of chloroma, and our consequently limited knowledge of the condition, leads me to publish a case treated at the Cardiff Royal Infirmary.

CASE-RECORD

A married man aged 25, a carpenter, was admitted to the infirmary on Oct. 15, 1937. Apart from scarlet fever in childhood he had always been healthy, and there had been no relevant illnesses in his family. About three months before admission he began to complain of general malaise, backache, lassitude, and anorexia, with attacks of vomiting, "rheumatic" pains in all his limbs, and steadily increasing deafness. At the same time he noticed a small swelling over the mid-sternal region and another over the third left costal cartilage. These swellings were hard, painless and varied in size. Sometimes they almost completely disappeared to become noticeable again a few days later. Soreness of the gums and teeth developed simultaneously with severe backache which forced him to give up his work three weeks before admission to hospital. Later he had diplopia, and this was followed by dimness of vision and bleeding from the gums.

On admission the patient's temperature was 99·6° F.; pulse-rate 130 per minute, regular and of fair volume. He looked ill and was very pale and thin. His skin was moist and clammy. He was almost comatose and lay in bed listlessly with his legs drawn up to relieve the pain in the back. There was a lump the size of a hen's egg over the lower portion of the sternum and attached to it. His tongue was dry and coated. The tonsils were normal in size and slightly reddened. The gums were bleeding, but no ulceration was visible in the mouth or throat. No abnormality was noted in the abdomen apart from some enlargement of the liver and spleen. No physical signs were found in the heart or lungs. B.P. 126/18. The central nervous system was normal, except for some retinal hæmorrhages, with blurring of the disks and white patches of exudate. The lymph-glands in the left cervical, both axillary, and inguinal regions were enlarged, discrete and firm. Urine sp. gr. 1·020; much albumin; no Bence-Jones proteose.

Blood-count (Oct. 15): Hb., 16 per cent.; red cells, 1,200,000; colour-index, 0·67; white cells, 11,000.

Blood-count (Oct. 17): Hb., 14 per cent.; red cells, 800,000; C.I., 0·88; white cells, 17,000 (polymorphs 21 per cent., lymphocytes 37 per cent., myelocytes 42 per cent.). Many myeloblasts. Red cells showed anisocytosis and poikilocytosis. Bleeding-time, 13·5 min. Clotting-time, 6·25 min.

Aspiration of the tumour was attempted with a wide-bored needle, but nothing could be withdrawn. The tumour was subperiosteal and was semi-solid. The patient deteriorated rapidly, vomited a number of times, became weaker, and died four days after admission to hospital.

Post-mortem findings.—The body was very thin and extremely pale with a few petechiæ, mostly about the root of the neck. An old scar was noticed about the inner side of the right thigh above the knee. A swelling 1 in. in diameter was present over the lower end of the sternum. Tumour deposits were found in the ribs, the posterior surface of the sternum, and the lower dorsal, lumbar and sacral vertebræ. Most of these deposits were subperiosteal. There was also one subperiosteal deposit in the vertex of the skull. On section the tumours were green, quickly fading to grey on exposure. The tissue was of a firm consistence. The spleen was somewhat enlarged and soft with prominent malpighian bodies. The pulp was pink with dark mottling. There was no notable enlargement of the lymph-glands. The marrow of the upper end of the femur was hyperplastic and green, but in the tibia it appeared somewhat gelatinous.

Several petechial hæmorrhages were visible under the epicardium. Numerous deposits were palpable in the myocardium. The heart was left unopened and preserved as a specimen. No abnormality was found in the aorta or other vessels. The lungs showed several subpleural petechiæ, with some hæmorrhages into the lung substance of the lower lobes. Both lungs were œdematous. The gums were hæmorrhagic and there was some chronic tonsillitis. Many disk-shaped deposits were found in the stomach wall. The pancreas also contained masses of tumour. The liver looked pale but otherwise normal. Small deposits were also found in the kidneys and the right testicle. The nervous system was normal except for a tumour deposit in the dura mater of the right middle fossa.

Microscopical examination.—The deposits contained large numbers of cells of the myeloid type. The liver showed leukæmic infiltrations of the portal tracts. A lymph-gland from the neck showed an increase of "endothelial cells."

The disease was described by Allen Burns about 1821 (Burns 1823), but the name chloroma was first used by King in 1853. In 1910 Lehndorf collected and reviewed the data of some 73 cases reported up to that time. Brannan (1926) noted the details of a further 74 cases recorded between 1910 and 1926, of which he was satisfied that 56 were definitely chloroma. Kandel (1937) has since collected 80 cases reported between 1926 and 1936, though he was only able to confirm the diagnosis in 46 of these. This makes a total of 175 cases up to 1936. The literature since that year contains reports of about 12 more cases. Including the present case an aggregate of about 188 cases have therefore been reported since 1821.

PATHOLOGY

Chloroma is a rare type of leukæmia in which tumours are formed in the bones. These usually appear both under the periosteum and in the bone-marrow. The growths may be found in any bone in the body but the most frequent sites are in the bones of the face and skull, more especially in the orbit. The sternum, ribs, vertebræ and pelvis are common but less frequent situations. Infiltration of the soft tissue with tumour deposits is also an important feature—e.g., the liver, spleen, kidneys

muscles, lymph glands, skin, breast and ductless glands Brannan states that no tissue is entirely exempt from deposits except possibly the brain and spinal cord Critchley and Greenfield (1930) have described cases of compression paraplegia due to spinal meningeal deposits The case reported by Rothschild (1926) showed a focal cerebral lesion According to Kandel discrete tumours in neural tissue are not described The nervous system is only indirectly involved through pressure and circulatory disturbances due to the presence of deposits in the surrounding structures, such as the dura mater and spinal canal. However, sections sometimes reveal infiltrations of peripheral nerves, and this seems to be one reasonable explanation of the limb pains

The tumour masses usually have a green colour which fades on exposure to the air Rarely the colour is stable, and in some cases it is entirely absent The colour can often be restored if the tissue is immersed in hydrogen peroxide Glycerin is said to preserve the colour (Meyer and Berger 1924) The nature of the pigment is obscure It is believed to be a lipochrome and to contain iron Meyer and Berger have reported absorption bands in the spectrum at 645 and 490 Some writers have associated the colour with eosinophil cells, but there is no constant relationship between the amount of colour and the number of these cells present In fact, eosinophil cells do not seem to be present in large numbers either in the blood or the tumour tissues Ashanazy (1917) thinks the green colour is due to the myeloid cells Both he and other workers have sedimented the myeloid cells in leukæmia and chloroma and noticed that these cells had a green colour which slowly faded

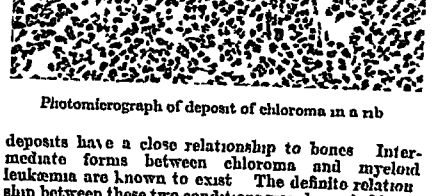
Blood changes.—Accompanying the tumour formation there are changes in the blood picture similar to those of acute leukæmia The leucocyte-count may be normal, about 8000 per c.mm., or may be increased to about 400,000 per c.mm., the majority of the cells being of the myeloblastic type (Burgess (1912) quotes 1,888,000 per c.mm. as the highest count and Pissavy and Richet (1912) 3200 as the lowest.) Many of these cells give a positive peroxidase reaction Some authors suggest that the results obtained in this test may vary with the method of performing the reaction and they advise that more than one technique should be adopted Occasionally the cells are reported as lymphoblasts, but most of these are now regarded as myeloblasts on more careful investigation The usual difficulties arise in differentiating the various forms of the more primitive leucocytes—a common problem in the interpretation of films in many blood diseases

The blood-count in some cases may resemble that found in aleukæmic leukæmia Brannan (1926) thinks that these counts are just phases in the disease, and that if sufficient counts are made in each case, a leucocytosis will be demonstrated at some time As in leukæmia, the blood picture may show changes similar to those seen in pernicious anæmia, with anisocytosis and poikilocytosis The bone marrow also shows evidence of red-cell regeneration

Other investigations that have been done, such as blood-calcium and blood phosphorus estimations, have been reported on as normal Only one author reports the presence of Bence Jones proteose in the urine

Microscopically the tumours are composed of cells similar to those seen in the blood—i.e., myeloblastic tissue (see figure) Lehndorff divided the cases according to whether or not the tumour tissue and the blood contained lymphoblastic or myeloblastic cells Burgess (1912) strongly maintained that the cells were myeloid in type Most writers now seem to hold this view The same difficulty arises in identifying the types of cells in the tumours, as in differentiating the leucocytes in the blood-films Myeloblasts and lymphoblasts both give a negative peroxidase reaction A positive reaction is, however, usually obtained, and this is explained by the presence of sufficient of the more mature leucocytes—pre-myelocytes and myelocytes

Unlike ordinary leukæmia, the tumour deposits infiltrate the tissues like malignant disease, and resemble deposits of another uncommon bone-marrow tumour, multiple myelomata Chloroma in its mode of tissue infiltration resembles lympho-sarcoma, except that in the former disease the



Photomicrograph of deposit of chloroma in a rib

deposits have a close relationship to bones Intermediate forms between chloroma and myeloid leukæmia are known to exist The definite relationship between these two conditions was shown in blood-films by Dock in 1893 The disease seems to be a variety of leukæmia, in which the changes found in the bone marrow have become so active as to suggest a neoplastic form of leukæmia. Our present knowledge of the disease does not seem to have advanced much since 1904 when Dock and Warthin wrote "Chloroma is a tumour like hyperplasia of the parent cells of the leucocytes, primary in the red marrow, the periosteum being secondarily involved The possibility of a primary chloroma in any part of the body in which white cells are formed must be considered" However, although deposits of chloroma possess local invasive characters similar to those exhibited by carcinomata and sarcomata, the mode of dissemination of chloroma throughout the body does not resemble the spread by lymphatics and the blood stream as in malignant disease

CLINICAL COURSE

The malady affects children, usually males, and less often adults The symptoms resemble those of acute leukæmia with the addition of tumours in connexion with bones. There is usually a preliminary period of malaise general weakness, wasting "rheumatic" pains in the bones, and some fever This is soon followed by changes in vision and hearing Simultaneously a severe anæmia develops with petechial hæmorrhages bleeding from the mucous membranes and septic ulceration of the mouth and throat The spleen liver and lymph glands are usually enlarged, though not invariable The retina may show hæmorrhagic exudates There are also palpable periosteal tumours and classical cases have orbital swellings causing exophthalmos Masses may commonly be felt on the sternum ribs and sometimes in the skin Huber (1878) and Simon (1912) each reported a case with signs of a malignant tumour in the breast and a radical amputation was performed

Another interesting case with signs resembling mastoiditis was published by Lewis (1919).

Reviewing the literature, the disease seems to present itself in two clinical forms: (*a*) that affecting children, in whom rapidly growing bony tumours are prominent, and usually called chloroma; and (*b*) that affecting older patients, in whom a progressive anæmia and signs of leukæmia are more predominant, and usually called chloro-leukæmia. In both types, however, the two essential features of chloroma are present—viz., leukæmic changes in the blood-films and green tumour deposits in bones.

Radiologically none of the appearances produced by chloroma in the skeleton can be said to be diagnostic. There may be periosteal elevation with new bone formation laid down in the striæ, either parallel or perpendicular to the shaft of the bone. Osteoporosis may either be generalised, or it may be seen as pin-point areas of destruction, as larger punched-out areas, or as erosions near the ends of the diaphyses. There are no changes in the epiphyses—a feature which distinguishes the condition from scurvy and rickets. Similar radiographic appearances to those of chloroma may also be produced by leukæmia, more especially the lymphatic variety, and by other bone diseases—namely, Ewing's tumour, osteogenic sarcoma, carcinomatous deposits, myelomata, sarcomata, congenital syphilis, and Hodgkin's disease.

The disease is always regarded as fatal. The average duration is about 6 months, but cases have lasted as long as 18 months. No effective treatment is yet known. Irradiation with deep X rays and radium have yielded no success, and appear to make the condition even worse. Drug therapy has produced equally bad results. Blood-transfusions only produce temporary benefit and do not stem the pathological process. Nevertheless two recoveries are recorded in the literature. In the case described by Lecene (1927) a green tumour was excised from the humerus and reported on as myelocytic chloroma, though the blood-count was normal. This was followed by deep X-ray therapy and the patient was reported to be alive and well 2 years later. Washburn (1930) described a case in a boy aged 22 months. A green tumour was excised from the skull and reported upon as a myelocytoma. Another tumour was present in the femur, and the blood-count was reported on as doubtfully leukæmic. Deep X-ray therapy was given. After treatment the blood was said to be normal. The patient was well 2½ years later. In neither of these cases does the diagnosis of chloroma seem to be strongly established, for the usually accepted criteria do not seem to have been fully satisfied. In both cases green tumours were described, but in Lecene's case the blood was almost normal, and in Washburn's patient the blood-films were not very definitely leukæmic.

SUMMARY

A typical case of chloroma is described in a young adult. The condition is rare, less than 200 cases having been reported since 1821. It is characterised by (*a*) the appearance in bones of green tumours composed of myeloblastic cells which infiltrate the tissues like malignant disease, and (*b*) a blood-picture resembling myeloblastic leukæmia. Tumour formation is the most prominent feature in children and progressive anæmia in adults. The disease is usually fatal within 18 months.

I wish to express my thanks to Dr. Herbert T. Evans for his permission to publish this case; to the staff of the department of pathology of the Welsh National School of Medicine for the post-mortem details and the photomicrograph; and to Dr. Marjorie Bryan, the house-physician of the case, for her help with the clinical notes.

REDUCTION OF POTASSIUM TELLURITE IN DIPHTHERIA

AND OTHER THROAT CONDITIONS *

BY K. E. COOPER, Ph.D. Leeds, L.R.C.P., A.I.C.
SENIOR BACTERIOLOGIST IN THE DEPARTMENT OF PREVENTIVE MEDICINE, UNIVERSITY OF BRISTOL

B. A. PETERS, M.D. Camb., D.P.H.
SUPERINTENDENT OF THE INFECTIOUS DISEASES HOSPITAL, HAM GREEN, BRISTOL; AND

J. WISEMAN, B.Sc. Edin., AND J. M. DAVIES, B.Sc. Edin.
ASSISTANT BACTERIOLOGISTS IN THE DEPARTMENT OF PREVENTIVE MEDICINE, UNIVERSITY OF BRISTOL

THE announcement of the possibility of more rapid diagnosis of diphtheria (*Lancet*, 1938) is always sufficiently important to demand investigation into the accuracy of the methods suggested. Dr. Alfredo Manzullo (1938) claimed that if a 2 per cent. solution of potassium tellurite, not more than a month old, were painted on the white exudate on the tonsil of a patient suffering from diphtheria, the membrane blackened within fifteen minutes—owing to reduction of the tellurite—but that no change took place in similar conditions such as streptococcal tonsillitis. He also claimed that a rapid bacterial diagnosis could be made in vitro by incubating a swab in a special liquid tellurite medium for three hours and observing black colonies on the swab in cases which were due to diphtheria, or the failure to produce any blackening in cases that were not.

We have compared the results of the in-vivo test with the clinical and bacteriological findings in a series of 84 cases and the results of the in-vitro test with the bacteriological findings in a series of 277 swabs. A swab (taken before the in-vivo test was made) was inoculated on the Löffler's medium, then on to a McLeod's tellurite plate, and then subjected to the in-vitro test. The bacteriological findings were obtained without a knowledge of the result of the in-vivo test, which was made by one of us (B. A. P.) along with the clinical observations. The result of the in-vitro test was recorded for each swab before a bacteriological diagnosis had been made and in the absence of clinical knowledge of the case. All strains isolated on McLeod's tellurite were typed according

* Based on a paper read at the Birmingham meeting of the Pathological Society on July 8.

to his classification (Cooper et al. 1936) Any case giving granular forms from Löffler when stained by Neisser, which failed to appear on the tellurite plate, was subcultured from the Löffler to tellurite and the strain isolated investigated to see whether it was diphtheria or a diphtheroid (Only 9 such swabs appeared in the 277 examined, and from 4 of them diphtheria was isolated The other 5 were apparently diphtheroids)

THE IN-VIVO TEST

Table I gives the results of the in-vivo test compared with the clinical and bacteriological findings "Severe" cases mean cases with extensive membrane and œdema of the neck in which the clinical diagnosis was certain "Moderate" cases are those with well marked membrane but no œdema of the neck. "Doubtful" cases include cases of follicular tonsillitis with patches of exudate, 1 case of Vincent's angina, and 1 case of agranulocytic angina with white sloughs on the tonsils In 57 cases where *Corynebacterium diphtheriæ* was found 55 were intermediate, 1 gravis, and 1 mitis

TABLE I—IN-VIVO TELLURITE TEST

Clinical condition	Bacteriologically positive		Bacteriologically negative		Total
	Reduction	No reduction	Reduction	No reduction	
Severe	17	5	2	1	25
Moderate	22	5	0	1	28
Mild or doubtful	5	3	15	8	31
Total	41	13	17	10	81

In the 25 severe cases in which the clinical diagnosis was certain there were 6 negative in-vivo tests In 2 other cases we failed to grow *C diphtheriæ* although the in-vivo test was positive We have not infrequently observed with this type of diphtheria that the original throat swab may be negative and may be followed later by a positive swab In 27 out of the 28 moderate cases *C diphtheriæ* was isolated, and 5 of these gave negative in-vivo tests Therefore, out of 52 definite cases of diphtheria, the in-vivo test failed in over 20 per cent of cases

Of the 8 doubtful cases in which *C diphtheriæ* was recovered 3 gave negative in vivo tests It might be that in these cases this organism was not the real pathogen A more noticeable feature of this group was the number of false positives—15 in which no *C diphtheriæ* could be recovered Of the 15, 4 were scarlet fever cases with patchy tonsils, 1 Vincent's angina, 1 agranulocytic angina, and 9 follicular tonsillitis If all the cases in which *C diphtheriæ* was recovered are included, the in-vivo test gave 13 false negatives out of 57 bacteriologically proved cases In the 27 cases in which this organism was not recovered the in-vivo test gave 17 positives, and probably 15 of these were false positives With such a high percentage error in both directions, it is doubtful if the test is of any great value

THE IN-VITRO TEST

The results of the comparison of the in-vitro test with the bacteriological findings are shown in table II In the results on 100 cases Manzullo (1938) does not include any doubtful reactions We have found difficulty in several cases in deciding whether his test was positive or negative, for indefinite grey discolorations appeared Such results have been separated from the definite ones and called doubtful, they have been excluded from table III entirely As regards nasal swabs, such reactions were usually on swabs which proved to be negative for diphtheria,

TABLE II—IN-VITRO TELLURITE TEST

—	Bacteriologically positive			Bacteriologically negative			Total
	Reduction	Doubtful	No reduction	Reduction	Doubtful	No reduction	
Throat	43 (68%)	13 (21%)	7 (11%)	34 (34%)	21 (21%)	44 (45%)	162
Nose	7 (28%)	1 (4%)	17 (68%)	12 (13%)	19 (21%)	59 (66%)	115

but as regards throat swabs they were more numerous and an equal percentage of bacteriologically positive or bacteriologically negative swabs gave doubtful reactions

Manzullo claimed accuracy for this method only as regards throat swabs and said that nasal swabs did not give satisfactory results Table II shows that 68 per cent of bacteriologically positive nasal swabs are negative by this test With throat swabs on the other hand, 88 per cent of bacteriologically positive swabs gave some darkening Thus suggests that factors other than the presence of diphtheria organisms are necessary for the reduction of tellurite Swabs soaked in pure cultures of diphtheria give no reduction by the test Preliminary experiments reported by Manzullo suggest that fibrin may play a part in the reduction The results on positive throat swabs do not in themselves suggest that the test is without value, but table II shows that bacteriologically negative swabs also give a positive test in 34 per cent of cases and a doubtful result in a further 21 per cent It thus seems probable that the reduction depends not so much on the presence of diphtheria

TABLE III—IN-VITRO TELLURITE TEST (EXCLUDING DOUBTFUL RESULTS)

—	Positive test		Negative test	
	Confirmed bacteriologically	Not confirmed	Confirmed negative	Bacteriologically positive
Throat	43 (56%)	34 (44%)	44 (87%)	7 (13%)
Nose	7 (37%)	12 (63%)	59 (77%)	17 (23%)

organisms on the swab but of organisms plus some additional factors, which are yielded by throats subjected to certain types of inflammatory reaction We hope to publish investigations now proceeding to determine the factors responsible for this reduction Manzullo says that after reading the results of the in-vitro test, they are confirmed by making films and staining by Gram's method We have found it impossible to distinguish *C diphtheriæ* from the diphtheroids usually present under these conditions The films showed an abundance of pleomorphic organisms, and we found no certain distinction between bacteriologically positive or negative swabs Some of the swabs giving most reduction of tellurite showed an abundance of fusiform bacilli and spirochætes suggesting that anærobic conditions were established during the three hours incubation, despite the fact

that the position of the swab provided for maximal aeration during the test.

If the results are expressed in another way and doubtful reductions are excluded, table III shows that we have failed to confirm the diagnosis of diphtheria in 44 per cent. of throats (and even a higher percentage of noses) giving a positive in-vitro test. Even with a generous allowance for the possibility of our failure to isolate the organisms in some cases of true diphtheria it is impossible to conclude otherwise than that many false positive reactions are given, which render the test of little value as an aid to the diagnosis of diphtheria. The sequence of the different examinations on each swab was such that possibly a few cases might be missed by the Manzullo test because the only organisms present on the swab were rubbed off by the inoculations on the other media before this test; but this could never cause false positive results (Control swabs impregnated with media and submitted to the test always remained white.) The occurrence of these false positives is also independent of the type of diphtheria present, though it must be remembered that, if other organisms play a part in the reduction, they may vary in type and distribution in different districts; hence the percentage error found in Bristol may not be universal. Nevertheless it is apparent that in some districts at any rate the test is misleading and of doubtful value. Until a knowledge of the factors contributing to the reduction is obtained, its real significance cannot be assessed. Seeing that "bacterial cultures are nearly always strongly reducing systems" (Hewitt 1935) during the early stages of bacterial growth, it is not unexpected that the test is not specific for diphtheria.

INSULIN PREMEDICATION IN CONVULSION THERAPY

BY DALTON E. SANDS, M.R.C.P.E., D.P.M.

ASSISTANT MEDICAL OFFICER AT CLAYBURY HOSPITAL (LONDON COUNTY COUNCIL), WOODFORD BRIDGE, ESSEX

THE purpose of this short paper is to demonstrate how a common difficulty in the use of Cardiazol and triazol in convulsion therapy for schizophrenia has been met at Claybury. I refer to the symptoms of resistiveness, fear, and panic.

Resistiveness is known to be one of the commonest features of schizophrenia, particularly in its catatonic form. One would therefore expect to encounter resistance in convulsant injections just as extensively as in other events; the more so when remembering that timidity is a common trait in the personality of the schizophrenic patient. Further, it is not unreasonable to suppose that such patients become frightened of a drug, the injections of which, they must eventually realise, will produce a loss of consciousness twice a week, even allowing for the fact that more alarming sensations are not recollected. In this connexion it is surprising to read Meduna's statement (1938) that only a few of his patients fear the cardiazol injection and none have exhibited the states of panicky fear described by some workers. Numerous writers in this country confirm the distressing nature of the sensations which the injections cause (Harris 1938, Russell 1938, Walk and Mayer-Gross 1938, Gillespie 1939), and my own cases have been no exception in this matter.

RATIONALE AND TECHNIQUE

It has always been the aim in convulsion treatment at Claybury Hospital to eliminate the "negative injection" so far as possible. In spite of this policy 12 patients developed considerable apprehension and states of panic after the completion of a few fits, even though the injection had always been promptly followed by a "grand mal" attack. To meet these difficulties, various sedatives were tried as premedicating agents to allay fear. Barbiturates and the once advocated morphine and hyoscine proved useless because of the large proportion of "negative injections" that resulted. Insulin has so far proved the most satisfactory agent in that it diminishes the patient's fear and facilitates the onset of the fit, with the result that the convulsion is effected with a smaller dose than before. Insulin has also proved beneficial in reducing the confusion and restless excitement which some patients show on recovery from a fit.

The object in insulin premedication is to give such a quantity as will induce coöperation with the injection of a convulsant drug. The dose may require pushing until drowsiness and languor supervene, but in 11 patients it has been possible to secure coöperation without the onset of obvious drowsiness. On such a basis it is clear that this form of medication differs entirely from the "summation therapy" of Georgi (1937), in which the coma-producing dose of insulin is first determined and the cardiazol injection planned to coincide with the "*turning-point*" in hypoglycæmia. A scheme of stepping up the dosage is used similar to that employed in insulin shock. The patient is started with ten units and the injection increased by tens until the desired coöperation is obtained. In 3 patients one could not say that the coöperation was entirely satisfactory, but resistance was so far decreased that the injection was carried through with little trouble. On almost every occasion the induction of the fit has been sufficient to dispel any lethargy induced by the insulin. The patients are given sugared tea to drink as soon as the fit is over. In 2 cases, owing to the development of insulin sensitivity, recovery was effected with glucose solution through the nasal tube on one occasion and with intravenous glucose on two other occasions. As with cardiazol therapy, the management of the premedication can be performed by the nursing staff of the ordinary mental hospital without the degree of special training necessary for insulin-shock summation methods.

RESULTS

Of the 23 patients dealt with in this paper 15 were given cardiazol, 6 triazol, and 2 cardiazol and triazol at different times. Since the present series forms part of a total of over 70 patients, and of this number 25 have been treated with triazol, it appears that triazol shows no particular immunity from the reaction which insulin premedication is designed to meet, though such has been suggested by some authors.

Insulin has enabled me to complete a course of convulsant treatment in 22 out of 23 cases, which courses would otherwise have had to be prematurely terminated because of resistance and apprehension. In case 3 the course was stopped because of the excessive exacerbation of symptoms on recovery from each fit. The patient's condition deteriorated,

and it was considered inadvisable to continue the treatment

Two points emerge from results summarised in the accompanying table (1) the high proportion of

RESULTS OF INSULIN PREMEDICATION IN CONVULSION THERAPY

		191	59	229	30			
Percentage of "negative injections"		30		13		Complete remission, CR 3 Improved I 14 No change NC 6		

* Discharged † Relapsed on trial

"negative fits"—namely, 30 per cent—which took place without insulin in these resistive patients was reduced to 13 per cent with insulin, and (2) there have been but 3 patients discharged in the small series, and 1 has since relapsed This is a very inferior figure compared with most of the published statistics and with the discharge rate for all cases treated at Claybury, which is about 42 per cent

SUMMARY

In patients undergoing convulsion therapy with cardiazol or trizol, the development of resistiveness, fear, and panic during treatment has been noted Sedatives such as morphia, hyoscine, and the bar biturates proved unsatisfactory in allaying these symptoms, on account of the "negative injections" which resulted Insulin premedication not only proved effective in obtaining coöperation in 22 resistive patients but also reduced the incidence of confusion and excitement on recovery from the induced fits This use of insulin, by greatly diminishing the unpleasantness of convulsion treatment to resistive schizophrenic patients, has facilitated their nursing and management

I wish to thank Dr J S Harris for his advice and for permission to publish this paper.

THE USE OF PENTOTHAL ACID IN MIDWIFERY

By G C Steel, M R C S, D A
ANÆSTHETIC REGISTRAR AT THE MIDDLESEX HOSPITAL, LONDON

Various methods of relieving pain during parturition have been tried and acclaimed, only too frequently to fall into disrepute At present most of the patients confined in institutions or hospitals in this country and many of those who elect to bear their children at home receive gas and air from one of the machines now available The analgesia is usually started at the beginning of the second stage of labour, and good results are obtained in most cases During the first stage, however, the mother undergoes a genuine discomfort which gradually increases in intensity, especially in primiparæ, who become progressively more apprehensive and perhaps exhausted as the pains mount to a crescendo Efforts therefore have been made in the past to produce analgesia and/or amnesia and have met with various degrees of success Twilight sleep, in which morphine and scopolamine were employed, and the use of Nembutal are probably the two best known methods which have been tried In the former, narcosis of the infant was frequently found (Burrows 1933), and in the latter, restlessness was noted in 20 per cent of the patients (O'Sullivan and Craner 1932), with prolongation of labour in other cases

The oral use of Pentothal Sodium as an analgesic and hypnotic in labour has already been reported on by Macphail, Gray and Bourne (1937), who have declared themselves satisfied with the results they have obtained For the sake of convenience of administration, it was decided that the use of a slightly more stable form of this drug would be expedient In response to inquiries the manufacturers very kindly produced a large supply of the more stable compound, Pentothal Acid

With the aid of the staff of the maternity unit I have administered this drug orally to a series of 200 women in labour at the Middlesex Hospital, having in mind the following criteria (1) the drug should not cause any excitement or have any harmful effect on the mother or on the fœtus, as evidenced by fœtal distress before birth, or by fœtal narcosis after birth, (2) a reasonable degree of analgesia and/or amnesia should be attained, and the drug should be easily administered and should not necessitate the constant presence of a qualified medical man in view of the possibility of sudden untoward occurrences, and (3) labour should not be prolonged In these 200 cases we have had very gratifying results, and we feel that, when properly used and with its limitations realised, pentothal acid will be very beneficial in the relief of the pains of labour

TECHNIQUE

When the pains begin to cause genuine discomfort, which is usually when they come on at intervals of five to seven minutes, the patient is given gr 6–8 of pentothal acid, this is repeated three quarters of an hour later From that point up to as near to delivery as is convenient for its administration, a dose of gr 2–4 is repeated every half to one hour, depending on the response of the patient, usually a dose every three quarters of an hour gives a good result

The mother usually becomes drowsy and sleeps between the pains, she wakes up with each pain but is not very distressed, and, so soon as the pain has finished, she again drifts off into a light sleep, from

which she can easily be aroused and will talk and answer questions in a perfectly intelligent manner. It is a pleasing experience to see a woman in the first stage peacefully sleeping between pains and yet waking up calm and refreshed as they recur.

At some time or another during the second stage we start giving gas and air to the patient. We have recorded instances when this has been refused. It is towards the end of the second stage that the value of the pentothal becomes most apparent. By the time that delivery takes place, the patient has usually had gr. 25–35, and the full benefit of the drug is then realised: in 80–85 per cent. of cases the woman is in a drowsy placid state, exhibiting a degree of quiet and willing coöperation that is indeed gratifying, obeying the obstetrician's orders while the pains are present, and resting quietly in between them.

RESULTS

We have not been able to detect any signs of harm coming to the mother through the employment of this technique, and, although in 7 per cent. of our cases we have been unable to reduce to a state of absolute coöperation already wildly excited members of our Soho clientele, we have yet to witness a case in which this drug has actually caused excitement. We lay special emphasis on this point, for, even when certain drugs may cause excitement in only a small percentage of cases, it is the uncertainty of not knowing whether or not each case that comes along will be a good one or a bad one in this respect that worries the obstetrician and the anæsthetist.

In our 200 cases we have had 5 stillbirths: in 4 of these tentorial tears were found post mortem, 3 of the 4 patients having been delivered by forceps; in the 5th case there was a tight knot in the cord with no pulsation palpable on the fœtal side of it. Not even by the most exacting standards, therefore, could these deaths be traced to the effects of the drug. Apart from these, all the babies in the series have breathed spontaneously, in most cases as soon as the head was born. This absence of respiratory depressant effect in the child has already been noted, in reports on the intravenous use of pentothal, both by Solomons (1936) and by Kassebohm and Schreiber (1938)

The degree of analgesia attained is good, but the degree of amnesia, although variable, is not great; at first we were disappointed about this, but latterly we have revised our opinion for two reasons: (1) we have come to the conclusion, as a result of questioning our cases, that most women do not want the birth of their child to be an "absolute black-out" in their memory; and (2) we feel that, if the drug gives a good degree of analgesia, the need for anything more than a slight degree of amnesia, a bemusement of the senses, is automatically cancelled The amount of genuine relief obtained by the summation of partial analgesia and partial amnesia is very considerable

The duration of labour is not, so far as it is possible to say, lengthened by the administration of pentothal; often indeed it appears to be shortened, owing possibly to increased tonicity of the uterus It is because of this possibility of increased tonicity that we refrain from administering pentothal acid to cases of trial labour until it is certain that the head will go through, and to occipitoposterior cases until the head is rotated. The only other contra-indication to the use of pentothal is toxæmia of pregnancy

Invariably have we found that the more intelligent the patient and the more willing to coöperate, the better are the results Some women are determined from the outset to extract the last ounce of dramatic value from their labour, and we fear that in these cases little can be expected in the way of good results In the case of a woman who is willing to coöperate, however, results are good, and to obtain this result it is essential that the woman be told that she is being given a drug which will help her to sleep between the pains and will ease the pains when they come on. She should be further instructed to close her eyes at the end of each pain and to "allow" herself to go to sleep. There is no need to darken the room, but the patient should not be distracted by having strong sunlight pouring into the room and should be subjected to as little questioning and examination as is possible.

The forceps-rate in the series was 13 per cent. compared with 12 per cent. for the corresponding period last year. The ratio of primiparæ to multiparæ was 79 per cent. to 21 per cent.

Although we have stated the usual total dosage to be gr. 25–35, we have given up to gr. 65 with no untoward effects upon mother or child.

It is hard to differentiate between any of the excellent gas-and-air machines on the market, but we have found that the Wellhouse model, as described by Elam (1938), gives good results.

We have no hesitation in giving pentothal to any normal case of labour and have never regretted having done so, the results being eminently satisfactory in almost every instance

SUMMARY

(1) Pentothal acid has been given to a series of women in labour in an attempt to ease their ordeal.

(2) The results have been very good: no harm comes to mother or child and labour is not prolonged.

(3) The patient sleeps between the pains and experiences a reasonable degree of analgesia; there is also some amnesia

(4) The patients are almost invariably extremely coöperative during delivery.

(5) The administration of pentothal acid is simple and special precautions are not necessary

My thanks are due to Mr. L. Carnac Rivett, Mr F. W. Roques, and Mr. W. R. Winterton for permission to administer pentothal to the patients under their care. I am also very grateful to the house-surgeons, sisters, and nursing staff of the maternity department for their unfailing assistance and their many useful criticisms. The pentothal used in this series was kindly supplied in 4-grain tablets by Abbott Laboratories Ltd.

THROMBOSIS AFTER INJECTION OF PENTOTHAL SODIUM

By Frankis Evans, M.B. Lond., D.A.
ANÆSTHETIST TO ST BARTHOLOMEW'S HOSPITAL, ST MARK'S HOSPITAL, AND ST. PETER'S HOSPITAL, LONDON

Periodically cases are reported in which extensive thromboses occur in veins after the intravenous injection of Pentothal Sodium For this reason the strength of the solution injected has been reduced from 10 per cent to 5 per cent. However, experience shows that even with this weaker solution thrombosis does occur occasionally, as in the following case.

The patient was a man of middle age, stocky of build, and well covered. He was obviously of sedentary habit but had no organic lesion of the

vascular or respiratory system He came under my care after a decision to manipulate his spine For this purpose he was given Omnopon gr ½ and scopolamine gr 1/150 by hypodermic injection half an hour before the intravenous injection of pentothal sodium 0 5 g in a 5 per cent solution The injection was made cleanly and easily into a prominent vein in the antecubital fossa, it took less than two minutes, and no fluid was allowed to escape around the vein Forty-eight hours later the vein was tender and hard, but there was no redness or swelling round it On discharge the patient had a hard cord, which was obviously the thrombosed vein, running up towards the axilla for some five inches, but it was no longer tender or painful

Thrombosis is the penalty frequently paid for long continued intravenous therapy, such as the postoperative use of saline, and this is not altogether unexpected However, when thrombosis occurs after the injection of a 5 per cent solution of pentothal, which only takes two minutes at the outside, it gives us cause for serious reflection It will be interesting to note whether the use of a weaker solution averts this unpleasant occasional sequela

MEDICAL SOCIETIES

ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION

(Concluded from p 202)

AT the meeting of the association on July 13 and 14, Dr E A CARMICHAEL (London) opened a discussion on the

Physiopathology of Epilepsy

He said that, besides the sympathetic nervous system, other factors controlled cerebral blood vessels, such as local intra arterial pressure and gas tension and adrenaline like and choline like substances There was as yet no positive evidence to support a theory of vasomotor disturbance as a causal agency He showed tracings giving evidence of systematic disturbance during a convulsion

Mr G D GREVILLE and Mr TUDOR JONES, Ph D (Runwell), in a paper on water metabolism in essential epilepsy, described the diurnal water exchange in two patients over about four months and in a third patient over one month Similar measurements were made on two non epileptic patients as controls No certain evidence was obtained that the urinary excretion was decreased before a fit and increased afterwards, as has been often claimed The water balance was determined daily The daily excretion of chloride in the urine under constant salt intake at two levels also failed to show any relation to the incidence of fits Serial investigation was also made of the concentration of blood constituents which might be affected by changes in the water content of the organism—plasma protein and non protein nitrogen, haemoglobin and total solids in whole blood Here again the variations were apparently unconnected with the incidence of fits contrary to the findings of other workers

Dr D J WATTERSON (London) described his studies on convulsive phenomena and the effects of cerebral vasodilator drugs Two recent pieces of evidence lent support to the so called vasoconstrictor theory of convulsive states the histological finding that the Cardiazol convulsion in cats is preceded by a generalised or circumscribed narrowing of the cerebral blood-vessels, and the observation that certain drugs which cause cerebral vasodilatation inhibit hypoglycaemic convulsions in dogs and, under certain circumstances, cardiazol convulsion in man Convulsions were induced in guineapigs by the intramuscular injection of cardiazol These closely resemble those produced by intravenous injection, but the convulsive phenomena are spread out over a period of minutes The convulsion is accompanied by a profound fall of pulse rate and change of heart rhythm These events are not associated causally with the convulsion The administration of choline derivatives does not inhibit the convulsions When amyl nitrite is administered, between the time of injection and the point at which convulsive phenomena might be expected, the chance of convulsion occurring is greatly enhanced

Dr A MEYER (London) said it was now widely recognised that the histological changes in idiopathic epilepsy were secondary to the convulsions and not their cause The lesions are due to ischaemic necrosis, and some of them are in characteristic regions Epileptic convulsions set up secondary lesions in the brain which may give rise to mental and neurological disorders The danger is greatest in infancy and early childhood, and W. Scholz has suggested that mental defect and other characteristic infantile conditions may be caused more often than realised by epilepsy The ischaemic changes have been taken as evidence of a vasoconstrictor pathogenesis of the fit Recently Scholz and his collaborators have tried to show by means of a benzidine stain, anaemia of the brain immediately preceding cardiazol convulsions in cats Dr Meyer showed slides suggesting that other than purely vascular conditions must be responsible for the histological changes observed after fits

Mr W GREY WALTER (Bristol) said that the only prominent feature of the normal electro-encephalogram (E E G) is the alpha rhythm, which comes from the parieto occipital cortex and is seen usually only with the eyes shut and the mind at rest The other parts of the brain do not normally produce any regular rhythms In certain neurological conditions, especially cerebral tumour and epilepsy, the affected part of the brain produces slow waves easily distinguished from the normal discharges, these are called delta waves In cerebral tumours, the tissue responsible for the slow discharge is not the tumour itself but the neighbouring cortex, which has been interfered with by the new growth, and there is some indication that the cortex produces delta waves in certain intermediate stages of dystrophy or degeneration, and these are often associated with oedema in the neighbourhood of the tumour It has been found that in "people complaining of fits" whatever the causes may be about 50 per cent show an abnormal E E G, and of those with abnormal records the great majority are clinically idiopathic epileptics, of these the great majority will be under 40 years of age Cases with a well authenticated history of trauma do not usually show any abnormality, it is probable that the slow delta discharge is an indication of fundamental cortical abnormalities which would not be expected in a patient with a splinter of bone or contracting scar causing mechanical cortical irritation In epileptics the abnormality of the E E G is a

continuous delta discharge similar to that found in cerebral tumour, but usually qualitatively different. This discharge goes on continuously and is not affected greatly by the administration or withholding of drugs, although it does show spontaneous fluctuation in size associated with fluctuations in the frequency of fits If the E E.G. is taken during a fit very dramatic changes can be seen. Lennox and his collaborators in Boston distinguish three types of seizure discharge · a smooth slow rhythm of high potential associated with "psychomotor" attacks, a slow rhythm with sharp spikes associated with "petit mal" attacks, and a fast rhythm associated with "grand mal" attacks They have also found, and this has been confirmed by many workers, that in a number of cases "sub-clinical" seizures can be detected by electro-encephalography even when the patient is unaware of the attack; only by careful and continuous observation of the patient's performance of some intricate task can these be detected clinically. The discovery that most young idiopathic epileptics show an abnormal resting E.E.G. can be of great assistance, not only in diagnosis but in prognosis, and in following the results of treatment. It may be said without reservation that a delta discharge in the E E.G. of a patient, complaining of fits or showing a spasmodic behaviour disturbance, is a certain indication that the patient is suffering from, or is likely to suffer from, idiopathic or essential epilepsy, and the prognosis is that associated with this condition Conversely a normal E.E G, although not a certain sign of normality, is suggestive of the possibility of some element other than epilepsy, and the prognosis is correspondingly better than if the E.E.G. is abnormal In a patient in whom hysteria is suspected the diagnosis can be clinched by inducing a fit. If the E E G remains normal the fit is not a true epileptic one.

Mr. N W. DOTT (Edinburgh) gave a general review of the surgical aspects of epilepsy.

Social and Therapeutic Aspects of Epilepsy

Dr J. TYLOR FOX (Lingfield) said that treatment of epileptics should begin at a well-equipped residential neurological centre, whence the cases could be classified into certain broad groups to be dealt with on different lines Epilepsy has grave social implications, and if treatment, in the wider sense, is to be effective, there must be a link between the patient in his home and the physician. Psychiatric social workers are very important in completing the scheme of treatment

Dr G. E. GRAVES PEIRCE (London) discussed the problem of the epileptic in industry

Dr. W. MCCARTAN and Dr. J. CARSON (Haywards Heath) spoke on the use of sodium diphenyl hydantoinate in epilepsy Putnam and Merritt set out to find the ideal anticonvulsant in a large series of animal experiments; they first established the "convulsion threshold" of different animals to electrical stimulation, and then produced variations in this threshold by various methods Of a series of about 100 different chemical compounds, some of them fairly closely related to sodium diphenyl hydantoinate, they found the latter most efficacious, having regard to its high anticonvulsant properties, its comparatively low toxicity and the absence of sedative effect The results of their clinical application of this drug, which has been marketed in the United States under the name of Dilantin, and later in England under the name of Epanutin, have been most encouraging, and the results in the Brighton Mental Hospital correspond, although the time available since the publication of Putnam and Merritt's work has not made it possible to try the drug in a large series of cases or over a long enough period. There is a close chemical relationship between sodium diphenyl hydantoinate and phenyl ethyl hydantoin, otherwise known as Nirvanol. This latter drug has been used in the past in the treatment of epilepsy on the Continent, and more recently in the treatment of chorea Poynton and Schlesinger have described the uses of nirvanol and its toxic effects. Some of the latter correspond with the toxic effects of sodium diphenyl hydantoinin, but no suggestion of the serious blood changes occasionally produced by nirvanol has been found in repeated blood examination of patients treated by epanutin

Dr. C G. MILLMAN reported on five years' experience with Prominal as routine treatment for epileptics The Cell Barnes colony had been opened for the admission of mentally defective patients in March, 1933. Until February, 1934, Luminal had been used in the routine treatment of epilepsy; since then prominal had been used In July, 1937, a report had been published comparing the results of treatment with the two drugs in a series of 39 cases Collectively the number of fits with prominal had been found to be approximately a third of the number with luminal Improvement in behaviour had been noted in many cases Individual results had shown much variation; most of the patients had improved with prominal, some had shown little change, and a few had become worse. Dr. Millman now discussed the subsequent history of those remaining; on the whole, improvement had been maintained Prominal had been used in 154 cases; the records of these had been examined and points of possible interest coordinated Two fatal cases of uræmia possibly due to prominal were reported and subsequent precautions described A case resembling aplastic anæmia developing in a patient under treatment with prominal was described, although the condition was probably coincidental. The effects of substituting soluble phenobarbitone for prominal in 32 low-grade cases were discussed Results of treatment in 16 cases over a period of one year with each drug were shown to be slightly in favour of prominal The economic factor was considered. An attempt was made to define the type of case most suitable for prominal Findings, though equivocal, suggested that high-grade patients with relatively few fits at regular intervals responded most favourably, whereas unsuccessful cases included a number of psychotics The possibility of a classification on therapeutic grounds was suggested.

Dr ISAAC FROST dealt with the use of sodium diphenyl hydantoinate in the treatment of epilepsy, with observations on severe cases After favourable reports had been made by Merritt and Putnam on the use of this drug in convulsive disorders, Dr. Frost had tried it in 12 cases of epilepsy, in which there were 60 to over 1000 major fits a year. Observations so far had extended over two or three months. In 2 cases there had been an apparently complete remission of major attacks, and 2 others had averaged 1–2 fits a month. In 5 others the reduction in the number of fits had been over half. In the remaining 3 cases, though there had been a reduction in the number of attacks, the results had not been striking Previously unrecorded minor toxic symptoms had been noted—e g, epistaxis, nodding of the head, and myoclonic phenomena "Epileptic equivalents" did not seem to be so well controlled by the drug, though in the favourable cases the mental alertness was in great contrast to the dulling effect of the usual anticonvulsants

Prof. F L GOLLA summarised the papers and emphasised the factor of cerebral excitability and its variations in epilepsy

REVIEWS AND NOTICES OF BOOKS

Orthopædic Appliances

By HENRY H JORDAN, M D London Humphrey Milford, Oxford University Press 1939 Pp 412 21s

THIS book ought to be in the hands of the surgeon who is inaugurating or in charge of a splint workshop, as well as accessible to the head mechanic, for it gives minute and practical details of the construction of every important piece of apparatus These are illustrated by first class photographs and line drawings The author uses great judgment in his selection of apparatus, he has drawn his ideas from both sides of the Atlantic, and has added ingenious designs In a foreword Dr E G Brackett agrees with the author that the proper selection and final adjustment of an appliance are as essential as is the detail of the operative treatment, and that knowledge, skill and personal supervision are required for its proper use If this book induces its readers to give more attention to acquiring such skill it will have benefited an enormous number of patients

In the section on spines, the author rightly stresses the difficulties of supporting this complex and mobile region of the anatomy He points out how essential it is to prepare a plaster of paris model of the trunk, on which to construct the apparatus, such a model being made and adjusted by the surgeon, who alone can judge its fundamental features In Britain this stage is often left to brace makers, nurses, or inexperienced residents The designing of such a brace demands constructive thought, as well as good judgment and skilled workmanship He divides spinal supports into supporting and corrective, but agrees that there is a very limited field indeed for the latter, as practically all correction should have been completed before a removable brace is prescribed Further, rigid supports are more comfortable than flexible ones He stresses the important principle of 3 point pressure for nearly all braces, all trunk apparatus must take its base on a well fitted "pelvic cage" He does not recommend the celluloid corset, which seems so popular in spite of its essential weakness and lack of adjustability He illustrates and recommends a number of Hohmann's ingenious devices, which are not easily accessible to the English speaking surgeon, and therefore are not as widely used as they should be These include the cork and celluloid buttress, which has revolutionised the treatment of neglected kypho scoliosis, the spiral iron for lower limb apparatus, including the valuable club foot type, and some for the upper limb

The author insists on a point which the professional instrument maker is loth to recognise—namely, that the introduction of joints into apparatus adds greatly to its weight and only in exceptional cases has compensating advantages The importance of controlling the trunk when fitting shoulder abduction splints is noted, a thing commonly neglected, and the author illustrates an effective and simple piece of apparatus of his own design for traction on the upper arm There is also a clear description of simple knee and ankle supports of leather, made on the principle of the many tailed bandage

In a book of this size from the U S A one would have expected an account of Goldthwait's various simple and extremely valuable spinal supports yet the author entirely ignores them Can it be that the city of Boston has not been heard of in New York? There are some smaller omissions of useful devices that might well be included in a later edition Among these are the "banjo" traction splint for stiff fingers, which proved so valuable in the late war, a grid over a radiator for drying plaster of-paris casts, and a blacksmith's tongs for spreading open a cut plaster before removal and for moulding in turned edges

The Chemistry of Milk

(2nd ed) By W L DAVIES, Ph D Camb, D Sc Wales, F I C, research dairy chemist and analyst, National Institute for Research in Dairying, Shinfield, Nr Reading, assistant for research in dairy chemistry, University of Reading London Chapman and Hall 1939 Pp 531 25s

GROWING realisation of the unique importance of milk and its products in human nutrition has led to increasing interest in its fundamental chemical and biochemical problems The new edition of this book gives an up to date and complete account of most aspects of this general theme Though new information has been incorporated where necessary, the author does not always give the latest available information on the chemistry of some of the minor constituents of milk, for example, in the case of vitamin B_1 The introduction of a paragraph on the hormonal control of milk composition is welcome, but recent work might have been more fully considered The section which will probably be of most interest to medical readers is that which deals with the nutritional value of milk This describes recent work on the thorny question of the effect of pasteurisation on the value of milk as a food

Unfortunately the book is still marred by frequent infelicities of English, such as, "This *period* of rapid oxygen-absorption is contemporaneous with the *region* of tallowiness" (our italics) Sometimes the writer's meaning is obscure, as in the following "The presence of olein acid makes the fractional crystallisation of the lower acids difficult and so is used only when an estimate of the higher saturated fatty acids is needed" Also authors' initials might have been given in the bibliographies which follow each chapter, and more care taken in compiling the author index Apart from these blemishes, which may readily be remedied in the next edition, the book can be strongly recommended as an authoritative and comprehensive account of the subject

Annual Review of Physiology

By JAMES MURRAY LUCK, editor and VICTOR E HALL, associate editor California Annual Reviews, Stanford University 1939 Pp 705 $5

THE volume of physiological "literature" which appears month by month has been sufficiently deplored, to describe it again would be to waste superlatives Let us admit at once that the title of this review is heroic and the conception admirable The result is a partial solution to the problem of the harassed scientist confronted with a menacing flood of print While some may be harassed more by the mental picture of themselves drowning in this flood than as a result of actually taking arms against a sea of troubles it cannot be denied that the problem exists Physiologists may already congratulate themselves on having at their service a comprehensive series of abstracts in German, brief abstracts in at least two English journals and two well known and other less known review journals Now this annual review appears which differs from the others in being

committed to survey recent work in every branch of physiology at one- or two-yearly intervals

The book will be of greatest use to the physiologist in his rôle of teacher. Most investigators find little difficulty in keeping up to date in their own field and would not be helped materially by these brief reviews which, though thorough, are not all comprehensive. But the editors hope, by changing the authors, to vary the approach to the different subjects—there are 24 sections, each by a different author—so that with the passage of time the series on any one topic will become increasingly valuable. In ten years' time they may be a godsend to the new research-worker Meanwhile it is not going too far to suggest that it is the duty of all who teach physiology to read the greater part of this book in order to acquaint themselves with progress in lines other than those which specially interest them. Sections on such subjects as radiation, genetics, developmental physiology, anæsthesia and physiological psychology look strange to English eyes (though one of them is written by an Englishman), but present boundaries have been determined largely by tradition and we can no longer afford to neglect advances in closely related fields.

The reader will encounter a variety of styles, ranging from Gesell's dramatic presentation of respiration and its control, to the skilful mosaic of Evans on endocrine glands, and the monotone of Bozler on muscle. The lasting value of the book will depend more on its successors than on itself. It is a good beginning.

A Bibliography of the Writings of Harvey Cushing

Prepared on the occasion of his seventieth birthday, April 8, 1939, by the Harvey Cushing Society. Springfield: Charles C. Thomas. 1939. Pp. 108. $5.

It is seldom that the writings of a medical man are sufficiently numerous to enable his admirers to prepare a Festschrift of this character. We have here the imposing total of 13 books and monographs and 306 papers In addition there is a list of 328 papers from Dr. Cushing's clinics and laboratories. Notes are appended to many of the entries explaining the occasions of addresses and lectures, and appraising the larger works

In a happily phrased foreword, Dr Arnold Klebs speaks of the functions of birthday cakes and explains the suitability of the present volume as a substitute This elegant tribute to a great man is limited to 400 copies

---

British Journal of Surgery

THE July issue contains the following articles:—

INCREASED and DECREASED DENSITY OF BONE, WITH SPECIAL REFERENCE TO FIBROSIS OF THE MARROW By H. A. T. Fairbank (London). Osteoporosis and osteopetrosis may be associated, or one may follow the other, in an individual case The common factor of fibrosis of the marrow is traced in various bone diseases Parathyroid dysfunction is suggested as the cause of renal rickets and of "marble bones"

IMPROVED SPINAL ANALGESIA. By Graham MacPherson (Hull). Light Percaine solution (1 in 1500 in ½ per cent saline) is the author's choice. He describes the technique he has used successfully in 513 cases and marshals his arguments in favour of percaine and of the use of a hypobaric solution

THE TREATMENT OF EMPYEMA THORACIS BY HIGH NEGATIVE-PRESSURE DRAINAGE By E R Trethewie (Melbourne). A historical survey of the treatment of empyema is followed by a discussion of the great advantages of closed drainage and of negative pressure. Eighteen patients on whom the author's method was employed all recovered.

VERITOL. A BLOOD-PRESSURE STIMULANT FOR USE DURING AND AFTER OPERATIONS. By Harold Dodd and Gerald Merton (London). From experience of its use in forty major surgical cases the conclusion has been reached that veritol is a reliable and satisfactory drug for restoring blood-pressure. Its action is transitory.

SPONTANEOUS RUPTURE OF THE GALL-BLADDER, WITH MASSIVE INTRAPERITONEAL HÆMORRHAGE. By Robert Mailer (Glasgow) At operation blood was found oozing from a rent in the gall-bladder adjacent to the liver From the absence of bacterial inflammatory change in this case and in 30 other acutely inflamed gall bladders examined the conclusion is drawn that the vascular changes associated with impaction of the stone are the most important.

VASCULAR ANOMALIES OF THE UPPER LIMBS ASSOCIATED WITH CERVICAL RIBS. By R M Hill (Keighley) Report of a case in which removal of the rib and of a fibro muscular band relieved pain, with diminution of swelling and improvement in the colour changes of the hand.

THE VASCULAR COMPLICATIONS OF CERVICAL RIBS AND FIRST THORACIC RIB ABNORMALITIES. By K. C Eden (London) Three cases are reported, two treated by excision of the cervical rib, and one by excision of part of the first rib. The vascular changes are said to be due to damage to the wall of the subclavian artery by intermittent pressure.

SUBLINGUAL DERMOIDS By Hamilton Bailey (London) The swelling occurs above or below the mylohyoid, and in either a median or a lateral position. Removal by incision below the angle of the jaw is advocated.

A CASE OF COLOCOLIC INTUSSUSCEPTION DUE TO DYSENTERIC ULCERATION. By Major F M. Collins (Vizagapatam). The patient, an emaciated Indian, had recurrent colic, with two attacks of acute dysentery He died after resection

SPONDYLOLISTHESIS By Wilfred Kark (Pontefract) In the case reported injury occurred eleven days before the radiogram was taken revealing the displacement. Reduction was effected by a combination of slinging the trunk in semiflexion with application of weight extension to the lower limbs.

THE SUPPORT OF THE SHOULDER: A NEW ABDUCTION SPLINT By W A Cochrane (Edinburgh). The body portion of the splint is a modification of the Goldthwait spinal brace. The abducted arm rests upon a supporting base formed by the pelvis and spine

SUCCESSFUL IMPLANTATION OF CUT PANCREATIC DUCT INTO THE DUODENUM. By D. J. Harries (Cardiff) The duct was cut during the freeing of the posterior surface of the stomach in a very difficult gastrectomy There were no complications from the anastomosis

CONGENITAL ABSENCE OF THE RIGHT FEMUR By Kamalakar Manohar (Bombay). Rudiments of the upper and lower ends were present, but neither hip-joint nor knee-joint A complete description is given of the anatomical findings at necropsy.

CONGENITAL DEFECT OF THE SHAFT OF THE FEMUR By H. H. Langston (Alton). Three cases are described of a congenital deformity due to retardation of ossification of the upper half of the femur. The condition is often associated with absence of the fibula and with bowing of the tibia The treatment is discussed

GALL-STONES AND CANCER: A PROBLEM OF ÆTIOLOGY, WITH SPECIAL REFERENCE TO THE RÔLE OF IRRITATION By Harold Burrows (London) Gall-stones from non cancerous patients were introduced into the gall bladder of 33 guineapigs. In 18 others various foreign bodies were introduced in combination with cholesterol or with carcinogenic agents. All the animals were allowed to die natural deaths and lived from 9–359 weeks None developed cancer. It is concluded that chronic irritation is not the cause of cancer of the gall-bladder

The issue contains an appreciation of the late Charles Herbert Fagge, and there are also short notes of rare or obscure cases.

CONTROL OF THE COMMON FEVERS

ERYSIPELAS

Reviewed by DR THOMAS ANDERSON, *deputy physician-superintendent of Ruchill Fever Hospital, Glasgow*

THREE years have now elapsed since Prontosil Rubrum (sulphamidochrysoidine) was first used in this country in the treatment of erysipelas The time is not unsuited, therefore, for a critical assessment of some of the factors involved in the control of this common disease

The clinical appearance of a case of erysipelas is too well known to require repetition here Comment may, however, be made on one point Formerly the condition was classified as either idiopathic or traumatic according to the absence or presence respectively of an obvious focus for the entrance of the infection Recently the knowledge of the bacterial origin of the disease has led to the assumption that all cases are traumatic in the sense that there must be a focus of origin, which might, however, be microscopic Although this observation is correct in lesions involving the limbs and trunk, it is not true of those involving the face, where most of the idiopathic lesions are seen Careful history taking in such cases reveals that in many of them the onset of erysipelas is preceded by a definite infection of the upper respiratory tract, tonsillitis, pharyngitis, and rhinitis, not infrequently accompanied by epistaxis, may be present for a period up to ten days before the dermatitis appears This fact has not received the prominence which it deserves, although it has been mentioned by some writers (Keefer and Spink 1936, Benson 1938) The explanation of this may be that only those cases which occur in surgical wards are usually transferred to fever hospitals, in Glasgow some 50–60 per cent of all notified cases are removed to one fever hospital. Under these conditions a considerable number of true idiopathic cases are constantly observed. In a disease whose clinical features are often upset by the presence of some complicating factor—infective, degenerative, or metabolic—the use of the term "idiopathic" to describe cases in which the onset is marked by an early acute inflammation of the upper respiratory tract separates a group more amenable to clinical comparison and bacteriological study

Bacteriology.—That erysipelas is a streptococcal infection is no longer in doubt Much labour has been expended in an attempt to prove that a specific streptococcus is responsible for it Most workers, however, now agree that the same streptococcus can be responsible for various diseases, and Okell (1932), producing case records to show the protean clinical manifestations of the same infecting agent, supports this so called "unitarian" hypothesis

The classification of strains from erysipelas by Lancefield's precipitin test or by Griffith's serological method has not been extensively practised The organisms are usually of Lancefield's group A (human) although Griffiths (1934) refers to a type VII strain as belonging to group C The occurrence of erysipelas in contacts of definite cases of scarlet fever and its association with this disease in small epidemics make it extremely unlikely, however, that there is any essential difference between the streptococci which cause the two diseases

Control.—Since erysipelas of trunk and limbs may be regarded as traumatic in origin and erysipelas of the face, when not traumatic, is usually due to infection of the upper respiratory tract, control is limited to treatment of the fully established disease and to prevention of recurrence (as distinct from reinfection)

RELAPSE AND RECURRENCE

An interesting feature of erysipelas which has defied an exact explanation is the relapse or recurrence so often seen Keefer and Spink (1936, 1937), Gay and Rhodes (1922), and Dochez and Stevens (1927) explain it by showing that after the primary attack the skin remains hypersensitive to the streptococcus or its bacterial products Keefer and Spink report a case in which a typical recurrence resulted after the injection, at some distance from the original lesion, of a toxic filtrate from the patient's own streptococcus Amoss (1931), commenting on the difficulty of isolating the infecting strain from recurrent cases, also suggests that second attacks may be due to bacterial products draining through the skin rather than to a fresh invasion Benson (1938) alludes to the possibility of septic foci remaining in the associated glands and paranasal sinuses as a cause of recurrence Up to the present, however, there has been no evidence to show whether the infecting strain of streptococcus in the recurrence is serologically the same as or different from that of the primary attack In this respect the absence of recurrence in cases receiving sulphamidochrysoidine or its congeners is, perhaps, a material fact Previously a direct antibacterial therapeutic approach was lacking Attenuated or degraded streptococci might remain in the tissues after the primary attack and be responsible for the recurrence During the course of an extensive investigation of the value of chemotherapy with these new drugs I noted that the proportion of patients admitted who had previously had an attack of erysipelas had progressively diminished throughout the period of the experiment (table I) The investigation was carried out in three consecutive series In the first and second every alternate case received treatment with sulphamidochrysoidine or its derivative, sulphanilamide, in the third all cases were so treated Table I shows a gradual fall in

TABLE I—RECURRENCE OF ERYSIPELAS

Series	Number of cases studied	Percentage of cases in which the patient had had a previous attack
1	312	23·6
2	270	19·3
3	242	15·6

the percentage of recurrent attacks during the period when an increasing number of patients were receiving the drugs The figures support the view that recurrence may arise from bacteria remaining in the tissues after the primary attack of erysipelas It is important in this respect to distinguish between reinfection and true recurrence A patient with a fungating cancer-oma or a chronic discharging sinus is constantly susceptible to a reinfection of the open site with haemolytic streptococci It is unlikely that any treatment could protect such a person from a repetition of the attack of erysipelas It seems, however, that with the new methods of treatment the recurrence previously so common in idiopathic erysipelas, is

one of the features of the disease which is now under control

PROGNOSIS

One of the difficulties is that there is no method of assessing the severity of erysipelas clinically. In some patients, despite an exceedingly angry-looking local lesion with moderate pyrexia, there is practically no other evidence of toxæmia; in others the local lesion appears to have little activity, although there is a high pyrexia with a severe toxæmia. Such variations are only seen when many cases can be reviewed by the same observer, and they demonstrate the difficulty of prognosis in each case

A further difficulty is that in an appreciable percentage of cases, although the initial efflorescence of the lesion in the first twelve to twenty-four hours may be active and rapid, the infection seems, in this short period, to reach the limits of spread. In such cases, despite the angry appearance of the lesion when first seen by the physician, further spread will not take place. There is unfortunately no method of foretelling when this will happen. In a recent series studied clinically, for the purposes of a therapeutic experiment, every third case admitted to the erysipelas wards received initially powders containing sugar of milk. In some of these cases the results of such treatment were recorded as "excellent." Spread of the lesion had ceased within twenty-four hours of admission in 35 per cent; and nearly 38 per cent. were afebrile after forty-eight hours in hospital. (These results do not merely represent the proportion of mild cases coming into hospital; some were assessed on admission as "severe" and many as "moderately ill") These figures demonstrate that the assessment of the value of any treatment is exceedingly difficult, and that any report suggesting that a certain therapeutic measure is efficacious must satisfy the following criteria: (1) the number of patients treated must be large; (2) there must be no selection of cases for treatment, all cases being included in the series studied, and (3) an alternative method of treatment must be used and patients entered to the two groups strictly in order of admission. Finally, when the results are assessed, it must be remembered that probably a third of the cases would have shown spontaneous cure in respect of spread of lesion and pyrexia within twenty-four to forty-eight hours of the start of treatment

TREATMENT

Although the easy recognisability and the fact that its course can be followed from day to day seem to make erysipelas an especially suitable disease for the study of the therapeutic efficiency, in man, of different methods of antistreptococcal treatment, certain points must be borne in mind. In streptococcal infections two main features may be noted: a toxæmia due to a diffusible exotoxin, the other due to that invasiveness which is a feature of the streptococcus. Longcope (1938) suggests that the variety, special character, severity, and outcome of hæmolytic streptococcal infections are determined by the predominance of one or other of the biologic properties of the particular infecting organisms and by the interaction of these forces on the varying resistance, immunity, susceptibility, or allergy of the host. In scarlet fever, for example, the early toxæmia and rash are due to circulating toxins, and some of the complications, such as suppurative adenitis, are due to invasion by the bacteria In erysipelas, on the other hand, the infection is dangerous by reason of its invasiveness into the tissues or blood-stream Birkhaug (1927), introducing anti toxic treatment, suggested that the results of his experiments presented a striking parallel with those reported by Dick and Dick in scarlet fever. Francis (1928) pointed out that on clinical grounds there was little reason for suggesting such a parallelism A comparison of the age-incidence in the two diseases alone suggests that the factors operative in them are not similar. The adoption of the "unitarian" view regarding the bacterial origin of the streptococcal infections has tended to involve a unitarian approach in regard to their treatment. There is reason for suggesting that treatment, to be effective, must be aimed at the particular feature of the infection which is uppermost, and, a priori, there is good ground for believing that scarlet fever and erysipelas, differing so much in their clinical features and pathogenesis, would not be amenable to similar methods of treatment

A review of the published reports of the treatment of erysipelas is not encouraging. One feels that to claim efficacy for a new method of treatment requires some audacity. No longer ago than 1928, Symmers claimed that the introduction of specific antitoxic treatment in erysipelas marked an advance whose results were only commensurate with those obtained by the antitoxic treatment of diphtheria. Parish and Okell (1928) showed that hæmolytic streptococci from various sources produced similar lesions when injected intradermally in rabbits, and they suggested that all hæmolytic streptococci were identical in their toxic action They further suggested that a single antitoxin (scarlet-fever antitoxin) could effectively neutralise this single toxin. It would be anticipated therefore that the therapeutic efficacy of "specific erysipelas" antitoxin and scarlet-fever antitoxin would be similar. The following experience does not appear to confirm Symmers's optimistic prediction.

TABLE II—RESULTS OF TREATMENT BY VARIOUS METHODS OF CASES JUDGED AS "VERY SEVERE"

Group	Method of treatment	Factor of assessment	Duration in days of spread of lesion and of primary pyrexia						Total cases in group
			0	1	2	3	4	5+	
1	Sulphamido-chrysoidine	Spread	7	6	3	2	1	0	19
		Primary pyrexia	0	4	6	5	1	3	
2	Ultraviolet light	Spread	0	2	5	2	2	4	15
		Primary pyrexia	0	0	1	1	4	9	
3	Sulphamido-chrysoidine+ ultraviolet light	Spread	1	4	3	0	0	0	8
		Primary pyrexia	0	2	1	2	0	3	
4	Scarlet-fever antitoxin	Spread	0	1	0	3	2	1	7
		Primary pyrexia	0	0	0	0	0	7	

Note—In the original investigation from which these figures are taken the number of cases in groups 1 and 2 was double that in groups 3 and 4

In a preliminary series of 312 cases treated, strictly in order of admission, with sulphamidochrysoidine, ultraviolet light, a combination of these two treatments, or scarlet-fever antitoxin it was noted that 19 had been classified by me as "very severe" on admission to hospital (Snodgrass and Anderson 1937a). A separate analysis of these cases (table II) shows that those treated with antitoxin gave the worst results

Colebrook (1935) suggested that patients with puerperal fever treated with scarlet-fever antitoxin did badly Later Kenny and Colebrook (1937) showed that most patients with puerperal fever

reacted negatively to the Dick test Many observers have noted that in erysipelas the Dick test is usually negative Since scarlet fever antitoxin is mainly if not entirely anti-erythrogenic, it seems that its administration to persons insusceptible to the toxin (as judged by the result of a Dick test) is unlikely to be beneficial

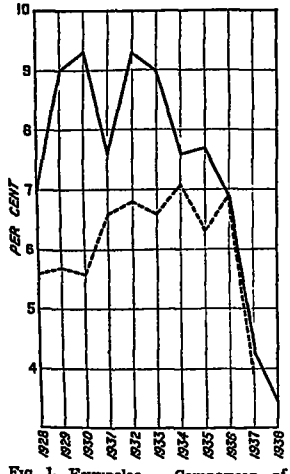

FIG 1—Erysipelas Comparison of death rate for England and Wales (interrupted line), calculated from the Registrar General's (England and Wales) Statistical Review, 1937, Part I, Medical, and case mortality in Ruchill fever hospital (continuous line)

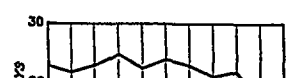

FIG 2—Average days' residence of erysipelas patients in Ruchill fever hospital during the same years

Chemotherapy with one or other of the sulphonamides has been extensively reported The great majority of these reports are in favour of the value of the drugs Few of them, however, satisfy the criteria enumerated above In fact in only two series of cases outside Great Britain has the number exceeded 100, and an alternative and concurrent control has usually been neglected Studies of 824 consecutive cases have been reported from Ruchill fever hospital (Snodgrass and Anderson 1937a and b, Snodgrass, Anderson, and Rennie 1938), and a summary of these results is shown in table III The figures leave little doubt of the efficacy of the new treatment

It has been suggested, however, that in the years preceding the introduction of sulphamidochrysoidine there had been a gradual decrease in the virulence of streptococcal infections, and that only part of the success of the new chemotherapy is due directly to the action of the drugs Fig 1 has therefore been prepared in an attempt to view the matter more objectively The graph shows that there has been so far as erysipelas is concerned, no obvious change in the case mortality for Ruchill fever hospital or in the death rate for England and Wales during the period 1928-36 The latter in fact suggests that there was a gradual though slight increase in the severity of the disease up to and including 1936 The drop in the 1936 case mortality at Ruchill is explained by the fact that from May, 1936, half the patients received sulphamidochrysoidine, though in rather small dosage These curves may be read in conjunction with that showing the average days' residence of patients with erysipelas in Ruchill during the same period (fig 2) (The average days' residence of patients in a fever hospital is not unsuitable figure for measuring the severity of a disease The constant demand for beds and the lack of visitation by relations make it certain that the patient is dismissed as soon as possible) There appears to be a close similarity between the three curves Such change as has taken place seems to have followed the introduction of the sulphonamide drugs and not to have preceded it There seem to be, therefore, reasonable grounds for presuming that the control of erysipelas by effective treatment is now an accomplished fact

TABLE III—RESULTS OF TREATMENT OF 824 CASES OF ERYSIPELAS

—	Cases treated by control methods	Cases treated with sulphanil amide or related compound
Percentage showing no spread after 24 hours in hospital	67 2	86 2
Percentage showing cessation of primary pyrexia within 48 hours of admission to hospital	50 3	75 5
Case mortality per cent	5·0*	2 8

* It should be noted that having proved in the first series of 312 cases that sulphamidochrysoidine was of value in the treatment of erysipelas thereafter patients responding badly to the control methods of treatment received a sulphonamide compound

Adequate chemotherapy cures erysipelas in practically all cases within three or four days The three preparations which have been most extensively used are prontosil rubrum (sulphamidochrysoidine), Rubiazol (carboxysulphamidochrysoidine) and *p*-aminobenzenesulphonamide The last mentioned drug is properly referred to as sulphanilamide, although it is often designated by different trade names

TABLE IV—DOSAGE OF SULPHONAMIDES IN ERYSIPELAS

Age group	Dosage in grammes per 24 hours		
	Sulphamido chrysoidine	Carboxy sulphamido chrysoidine	Sulphanil amide
Adults	9–12	2–3	6–9
5–10 years	6–9	1–2	4 5–6
Under 5 years	3–6	0 5–1	3

Table IV shows the range of dosage which should be employed in different age groups Children tolerate the drugs exceedingly well, and, since the disease is often most severe in infancy, relatively large doses may be administered, especially in the early stage of treatment To maintain an effective concentration of the substance in the blood, the drug should be given by mouth at four hourly intervals Preparations may be obtained for parenteral administration but show no therapeutic advantage over the oral route

If the suggested dosage is used the lesion will cease to spread within forty eight hours, and in most cases the temperature will return to normal within three or four days of the start of therapy Should this not happen, the diagnosis should be reviewed, the presence of some septic complication should be excluded and the question of fever directly due to the drug should be considered Full dosage should

be used until the temperature returns to normal, after which the drugs should be continued in a dose of 0·5–1 g. thrice daily for ten to fourteen days. When this is done, recurrence of the disease is unusual.

Finally, during the administration of these drugs certain rules should be rigidly applied (Snodgrass and Anderson 1937b) In such circumstances the toxic effects of the drug will be minimal. Reference should be made to the original papers for information about the toxic effects usually encountered.

CONCLUSION

In the present stage of knowledge the control of erysipelas depends on the adequate treatment of the infected patient with one of the sulphonamides. In such circumstances relapse and recurrence will become less frequent, although reinfection will not be prevented.

MEDICINE AND THE LAW

Police Complaint of Panel Doctor

THE Derby insurance committee last week disposed of what seems a novel point of panel practice The chief constable had formally complained of the conduct of a doctor in circumstances to which he took "strong exception." A man who was on the doctor's panel had been found dead. The police had informed the doctor by telephone, and at the request of the widow had asked him to call The doctor, it was said, had replied "I will call on my morning round You have a police surgeon; make use of him; I will give him all the assistance I can regarding the man's medical history" The complaint was referred to a subcommittee, to which the doctor gave a slightly different version of the facts The police, he stated, asked him to come round at once to pronounce life extinct, although they assured him that the man was dead and had been dead for some time before he was found. As nothing more could be done for the patient, he promised to call next morning to see the widow and to give his opinion on the cause of death; he did so and gave the police all the information he possessed He maintained that he was under no obligation to visit anybody at the request of the police, even if they guaranteed his fee As regards his duties under the terms of service, he always understood that death put an end to the patient's insurance.

Misunderstanding is always possible in telephone communications An insurance practitioner would presumably be right in challenging the authority of the police to summon him to view the body of a panel patient who had been dead for several hours On the other hand he would feel obliged to attend if the patient's wife sent for him because her husband was in extremis The chief constable told the sub committee that the doctor was wanted, on behalf of the widow, to examine the body because the police had no authority to pronounce a man dead The police sergeant who had sent the telephone message gave evidence that he told the doctor he was speaking for the widow On the other hand the doctor said that he did not understand that the police were calling him on the widow's behalf; that was why he suggested making use of the police surgeon if the case was urgent. The subcommittee's report seems to have supported the doctor's attitude The insurance committee, adopting the subcommittee's findings, decided to take no action in a matter which they considered to be outside their jurisdiction They decided that the doctor had not committed a breach of the terms of service.

Slander of a Medical Officer

If medical officers of health inevitably encounter hostility in the discharge of their duties, they ought at least to be protected from a campaign of abuse In a case recently heard in Dublin Dr. D. McCarthy, formerly county medical officer of health for North Tipperary, recovered substantial damages for defamation from Mr. Daniel Morrissey, who had accused him of furnishing a false report to the local authority. Dr. McCarthy was responsible to the North Tipperary board of health for the health and cleanliness of children attending elementary schools in the board's area. In March, 1938, he and his assistants examined the children attending the convent girls' school at Nenagh, and he forwarded his report to the board. He complained that in the following month the defendant declared on several occasions that the report was absolutely untrue "I know," the defendant was alleged to have said, "that there are children going to school who received a 'yellow ticket,' classifying them as dirty, but there were no cleaner children to be found in Nenagh, in Tipperary or in Ireland" The defendant, as a member of the Nenagh urban district council, moved a resolution strongly protesting against Dr McCarthy's report as "a scandalous reflection on the town and a gross slander on the mothers and teachers of the children of Nenagh" Dr. McCarthy contended that these words imputed impropriety, misconduct or incapacity to him in the discharge of his profession and his office, and he pleaded further that, owing to the slander, he had been unable properly to perform the duties of his office and was forced to resign it The defendant pleaded all the defences usual in such proceedings—denial that he spoke the works, denial of publication, denial that the words were defamatory, privilege as a district councillor, honest belief in the truth of the statements, and fair comment on a matter of public interest He also contended that the allegations were in fact true

Mr Justice Hanna upheld the plea of privilege in respect of one of the occasions when the words were uttered, but not in respect of another occasion The jury found in favour of Dr. McCarthy and assessed the damages at £600. The plaintiff's position as medical officer of health had clearly been made impossible and he is to be congratulated on the vindication of his character. A public servant who must report only what is palatable would be of little use to the community.

THE LANCET

LONDON SATURDAY, JULY 29, 1939

TOWARDS MENTAL WELFARE

THE best preparation of a people for peace or war must be soundness of body and mind In these days of suspended crisis much attention has rightly been devoted to the body, and the organisations that aim at promoting physical health are busily engaged in coördinating their efforts and making their schemes part and parcel of the educational system The physical fitness campaign may be regarded as the third stage in a movement which had its origin in the sanitary efforts of the pioneers of the nineteenth century and led on to the preventive medicine triumphs of the twentieth But physical fitness alone is a barren ideal it can bear no fruit unless it is mated with intellectual fitness This fact, too, is at last gaining recognition, but although mental health has become an object of public concern, there is as yet no single efficient organisation for turning this concern to practical ends Efficient and valuable organisations there undoubtedly are, but these have not been fully coordinated or their resources concentrated where most needed We have depended too long on the generosity of the Commonwealth Fund of America in carrying out functions that are our elementary duties as a nation Much of the work in this field has been done by voluntary bodies, so it was appropriate that they should take the initiative in establishing "a single directive force to guide the development of the service and to lay plans for future action on a united front" The committee which has met under the chairmanship of the Earl of FEVERSHAM has wisely gone beyond the immediate domestic matter of coordination or fusion, and has reviewed the whole problem of mental health in this country Its report is a pathetic record of our failure to undertake one of our most urgent social obligations The lack of an organised mental health service is serious enough in peace time, in times of stress it is a public danger of the first order

The clear and balanced report, of which a brief summary is given on p 274, deals comprehensively with this tangled subject It will be appreciated by all who have complained of the difficulty of seeing the wood for the trees The trees are indeed varied, some stubborn and gnarled, others luxuriant and even rank, with their interlacing roots and struggles for light and nourishment, leading to an obvious ecological problem The solution of this problem—how all the necessary kinds of psychiatric activity are to live together harmoniously—has been the chief business of the committee Seeing the matter as a whole, they can propose measures which take account of the public services of the Government or local authorities, and of the essential, if at present supplementary, services rendered by voluntary bodies There is a clear case for the amalgamation of the existing voluntary associations—the Mental After-Care Association, the Central Association for Mental Welfare, the Child Guidance Council, and the National Committee of Mental Hygiene The first of these bodies has declined to merge itself in the proposed National Council for Mental Health, but this has not hindered the Feversham committee from putting forward the general plan There is no aspect of mental health work which has not been touched on in the report, though administrative questions have received more attention than research, teaching, and clinical principles, all of which are fundamental to the developments foreseen

The recommendations cover a wide range Mental deficiency is an instance in which big alterations are recommended The experts will warmly support them It is proposed that the Mental Deficiency Acts should omit references to educational incapacity and adopt the criterion of social inefficiency, educational retardation being left to be dealt with under the Education Act, it is urged that defectives, like the mentally disordered, should be able to obtain institutional treatment voluntarily, and that the procedure for guardianship should be simplified and made less formal Welcome emphasis is placed on social aspects in the four chapters dealing with mental disorder, mental deficiency, delinquency and the mental health of children Few people who are not psychiatrists recognise how indispensable to efficient work in any of these fields is the psychiatric social worker, whose training and equipment are now highly specialised It is anticipated in the report that the demand for trained social workers will presently far exceed the supply, and it is therefore urged that similar courses to that provided by the London School of Economics should be arranged at the great teaching centres

Perhaps the most interesting recommendation of the committee is its advocacy of psychiatric clinics with inpatient and outpatient facilities In populous areas these would be special hospitals, and in smaller centres special blocks adjacent to the general hospitals Where a medical school is within reach, the special psychiatric hospital for early mental and "functional" nervous disorders should be established in close association with it There should, in short, be hospitals on the model already familiar in some university centres in the United States and on the Continent and in England represented by the Maudsley Hospital Such hospitals, in each of the university centres, would provide teaching facilities for medical men and psychiatric social workers, and in many ways would advance psychiatry throughout the country There would be, as the committee points out, close coöperation between the special psychiatric hospital on the one hand, and the mental and general hospitals on the other Grouping of mental health work on a regional basis, as is done with other branches of public health, and adjustment of the boundary between statutory and

voluntary activity, with greater cooperation between them, are obvious needs which the report puts with convincing objectivity. In its combination of enthusiasm for the main end and detachment from rivalries and partisan claims it is a document of great value, which will be of historic importance in the growth of the mental health services of this country.

ACTIVITY OF GONADOTROPHIC PREPARATIONS

ONE of the chief obstacles to the clinical use of gonadotrophic substances is the difficulty of securing accurate information about their biological effects in women. Much of the information on which therapy must be based has to be obtained from laboratory animals, and its value is greatly reduced because the response to gonadotrophic substances differs widely from species to species: what is true of one animal is not necessarily true of another—or of the human patient. This variation between species is, at least partly, attributable to the fact that the response of the gonads to gonadotrophic substances is sometimes modified by the concurrent activity of the animal's own pituitary, especially where the initial changes in the ovary, or the extract itself, stimulate pituitary secretion. Writing in the first issue of the new *Journal of Endocrinology*, NOBLE, ROWLANDS, WARWICK and WILLIAMS [1] take it as proved that the apparent response of the ovary of the immature rat to the gonadotrophic substance of human urine of pregnancy is largely caused by the hormones of the rat's own pituitary. In the intact immature female rat the ovary responds by enlargement of follicles (which may be followed by ovulation), and the formation of normal or atretic corpora lutea, or sometimes blood follicles. On the other hand, in immature rats deprived of their pituitary the only change in the ovary evoked by chorionic gonadotrophin is a diffuse luteinisation of the stromal and thecal tissue. This suggests that human urine of pregnancy contains but a single gonadotrophic substance, with a luteinising action; whereas, without experiments on hypophysectomised animals it would naturally be deduced that such urine has both follicle-stimulating and luteinising activity.

No-one can yet say how far the endogenous gonadotrophic hormones contribute to whatever effects follow the administration of gonadotrophic substances to women in whom there is reason to suspect hypogonadotrophism. It is unlikely, however, that the participation of the intact pituitary gland is as important in women as in rats. Information more relevant for clinical purposes might therefore be obtained by using experimental animals in which the pituitary has little influence. For this reason, as well as because of their blood-relationship to us, one would expect to get the most valuable information from a study of the effect of gonadotrophic preparations on monkeys, in which tests carried out on intact immature females have yielded little evidence of interference by the pituitary body. In a paper just published DE FREMERY [2] not only summarises existing information for this class of animals, but adds new and significant data. He has compared the effects on the ovary of immature macaque monkeys of gonadotrophic extracts from the pituitary of pigs and of human beings, from human placentas, from human urine of pregnancy and from human urine during the menopause. Of these various preparations the chorionic gonadotrophin was found to have no obvious action in the dosage used, and it seems therefore that in macaques, and possibly in all primates, this type of gonadotrophic preparation has no power to cause direct enlargement of the graafian follicle. Exactly the same lack of response was seen when extracts of human placenta were used—a result which supports the view that the substances of human urine of pregnancy and of human placenta are identical. Extracts from urine of the menopause stimulated the follicle slightly. With extracts of pig pituitary, however, strong stimulation of the follicle was observed; and there was no luteinisation, which is interesting because luteinisation is the chief effect of a pig-pituitary extract on the immature rat, or even the hypophysectomised rat. The effects of pig-pituitary extracts in monkeys further differed from those in rats in that the effectiveness of the extract was not increased by the simultaneous administration of chorionic gonadotrophin or by the Maxwell technique (admixture of zinc sulphate). Extracts of human pituitary gave intense follicle-stimulation, and it is noteworthy that the human pituitary, tested on monkeys as on rats, has a greater content of gonadotrophic material (per mg. of dried tissue) than the pituitary of any other species. Extracts of human pituitary, like those from the pig, produced no luteinisation in the immature monkey.

From DE FREMERY'S results it seems that immature monkeys of the kind he used are almost wholly irresponsive to luteinising substances, since extracts which are purely luteinising had no effect at all, and extracts which on hypophysectomised rats produce a dual effect stimulated only the follicle of the monkey. The significance of these observations is not quite clear, but they apparently imply that the clinical use of luteinising preparations, in the hope of stimulating the development of luteal tissue, should be undertaken with reserve, while the maturation of the follicle by such preparations is improbable. On the other hand, if the monkey results are applicable to human beings, one would expect to find that stimulation of the follicle could be achieved fairly readily in women by the use of those gonadotrophic preparations that evoke (mainly or exclusively) this effect in test animals. Such preparations are now commonly available in the form of the gonadotrophic extracts from pregnant-mare serum, and it is encouraging to know that clinical tests of this comparatively new and potent material are now being actively pursued.

THE EMERGENCY BLOOD-TRANSFUSION SCHEME TO DATE

THE first phase of an organised effort to provide a reserve of blood donors for London and the Home Counties in the event of a possible emergency came to an end on Saturday last. There is general agreement, strengthened by the lessons of the war in Spain, that blood-transfusion would play a major part in the treatment of air-raid casualties, hence the provision of an adequate supply of blood must be counted among the essential medical preparations for civil defence. The exigencies of casualty treatment during repeated air attacks might render blood matching, or even the determination of the recipient's blood-group, exceedingly difficult, there are obvious arguments for relying, in the main, on universal donors, and on a supply of stored blood. In this way it would be possible, given adequate supplies, to ensure that each casualty hospital would be able to perform a large number of transfusions with a minimum of delay. Here again valuable lessons have been learned from the war in Spain.

The inauguration of the sector scheme for emergency hospital services in London and the Home Counties provided an opportunity for planning a coördinated blood-transfusion service for this area, it was decided to establish four main depots—at Luton, Slough, Sutton and Maidstone—at which blood from universal donors could be collected, stored, and distributed to the London sectors. The Medical Research Council, acting on behalf of the Ministry of Health, undertook the organisation of these main depots. It was evident, however, that such depots could not be relied on to function during the first few days of an emergency, and that it would be unwise to leave the casualty hospitals without an alternative source of supply, even at later stages. It was therefore decided that, in addition to the donors required by the depots (most of whom would be drawn from the areas in which these are situated), a large number of volunteers should be enrolled and tested, who would be living, or working, in the more central areas of the London sectors. The organisation of this part of the scheme was deputed to a committee of sector-pathologists, working under the group hospital officers, the Medical Research Council acting only as a coördinating and advisory body.

The first essential was clearly the enrolment of an adequate number of universal donors, and this involved the grouping of a very large number of volunteers. Assuming the usual proportion of group IV blood (40 per cent., or a little over), and allowing for the migration that would probably occur in an emergency, the number of volunteers required in the London sectors alone has been estimated at about 100,000, and about an equal number would be required by the four depots. The depots, drawing volunteers from their immediate neighbourhood, were able to start the grouping earlier, and to envisage a long campaign of testing. They were aided by the British Red Cross, and by other voluntary organisations. The testing of volunteers in the London sectors was a more difficult undertaking. A wide appeal for donors meant the maintenance of many testing stations so that any volunteer could enrol at some station near his or her home or place of work. In the event it was found possible to maintain some eighty testing stations in the London sectors during the three weeks, July 3 to 22. Each station was open every week-day from 10–12 and from 5–8. The whole of this work fell, so far as the taking of blood samples was concerned, on the hospital pathologists, their technical staffs, and senior medical students from the teaching hospitals. The sacrifices demanded have been very great, since there could be no cessation of ordinary hospital activities, and the goodwill with which this added burden has been shouldered by all concerned is an example of what can be done by voluntary coöperation. It was necessary to provide an efficient clerical staff, in addition to the technical staff concerned in blood-testing, and here the Women's Voluntary Services have played a major part, supplying workers to assist at the testing stations and at certain central stations where much of the clerical work was done. On the appeal side, a group of publicity experts, the press, and the B B C all afforded help.

As the result of this coördinated effort some 50–60,000 volunteers have already been tested in the London sectors, apart from those tested at the depots. The campaign has made an excellent start, but it must clearly continue, though in London it must be at a less breakneck pace. Some thirty stations in the London sectors are remaining open, the hours of attendance being changed from 12 noon to 6 P.M., and the four main depots will continue to enrol and test volunteers until they have obtained the desired numbers. A list of these stations is available in every post office. In the provinces plans are not, in general, so far advanced. Here the service must clearly be developed on a local basis, in accord with local needs and opportunities, though it is expected that the enrolment forms and cards that have been used in London will be made available to local authorities through the Ministry of Health, and the apparatus devised for use in London and the Home Counties might with advantage be adopted elsewhere.

The appeals of the last few weeks have aroused the interest of the general public and have shown how readily people respond when told of an important service which any healthy person between 18 and 65 can perform.

The Privy Council have appointed Mr GERARD ROBERT HILL, C B, who recently retired from the Parliamentary Counsel's office, to be chairman of the Statutory Committee of the Pharmaceutical Society.

We regret to announce the death last Sunday of Mr ARCHIBALD YOUNG, regius professor of surgery since 1924 in the University of Glasgow. A week before, in view of his approaching retirement at the age limit of 65, he had been presented with his portrait by his colleagues and friends in Glasgow.

ANNOTATIONS

LONDON WATER

MEMBERS of the Paddington Medical Society who recently visited the Kempton Park works learned much about the London water undertaking Some 310 million gallons of water are consumed daily by a population of about 8 million The water is derived from the rivers Thames and Lee and from deep wells in the chalk or the greensand The well-water is of high organic purity and usually free from any evidence of pollution When however such evidence is present in the least degree the water is chlorinated before being passed into supply. The river water which provides four-fifths of the total is polluted before reaching the intakes, and to ensure that none of this pollution reaches the consumer this water passes through three stages of purification: storage, filtration and chlorination. The primary object of storage is the conservation of supply but its effect on the bacterial population of the water is profound *Bact coli*, which is the recognised index of sewage pollution, is usually present in 1 ml of raw river water, while after about thirty days' storage in a reservoir it may be absent in 10 ml or even in 100 ml The water reaching Kempton Park works comes from the Metropolitan Water Board's largest reservoir, the Queen Mary, which holds 6750 million gallons; water is pumped into this reservoir from the Thames at Laleham at the rate of about 100 million gallons a day. On reaching the works the water first passes through rapid mechanical filters designed to remove the grosser forms of suspended matter such as algæ and silt The visitors were shown these filters in operation and the method of washing them by air scour, followed by upward displacement of the accumulated deposit by water The secondary filters consist of 12 beds, each of about ¾ acre, composed of a layer of fine sand, 2 ft 6 in. thick, supported on shingle through which the water percolates downwards at the rate of 10–12 in an hour. When these beds become choked they are cleansed by hand, the top "skin" being skimmed off and passed through sand washers The effect of this filtration process is to reduce the *Bact coli* content to such a degree that two-thirds of the samples contain none in 100 ml In the final process of chlorination the water receives first a small dose of ammonia in the form of a solution of ammonium sulphate and then chlorine at the rate of 0·35 parts per million, the ratio of chlorine to ammonia being two to one The liquid chlorine is contained under pressure in large steel drums, the gas being passed through a measuring device and dissolved in water in a solution tower The solution of chlorine is then led to the general well through which all the water from the filters passes By means of chlorination a standard approaching 100 per cent of samples containing no *Bact coli* in 100 ml is maintained Finally the visitors inspected the engines which pump the purified water to service reservoirs from which it gravitates to the consumers.

STUDY OF EPILEPSY AT THE BURDEN INSTITUTE

THE study of epilepsy is entering on a new and hopeful stage. Striking evidence of this was the allocation of two days at the Brighton meeting of the Royal Medico-Psychological Association (reported on p 253) to the physiopathology of the disease and the directions in which the knowledge gained is leading therapeutic effort The great need is for prolonged and leisurely study and it is encouraging to learn that Mrs. R. G. Burden, who has already earned the gratitude of all engaged in neurological and psychiatric research by founding the Burden Institute, has now enhanced its value by endowing a hostel of 30 beds for patients undergoing investigation at the institute The hostel, which will be ready for use in a few months, is to accommodate patients in separate rooms with reasonable comfort At first it is proposed to reserve this hostel for cases of epilepsy and allied conditions The hostel will be under the control of a committee of the Burden Neurological Institute, the chairman of which is Sir Laurence Brock

NUTRITION IN THE COLONIES

IT has long been known that abundance and deficiency exist side by side in tropical climes—"malnutrition rife in a land of natural plenty," as a writer of Grains and Scruples [1] said of the West Indies—and this is borne out by articles published in these columns in the last two months on a deficiency of vitamin B_1 in East Africa,[2] a deficiency causing endemic glossitis in Palestine,[3] a deficiency of vitamin-B_2 complex in the Straits Settlements,[4] and a deficiency of vitamin A in Ceylon [5] In 1936 the then Secretary of State for the Colonies asked all colonial governors to report on standards of nutrition in their territories On receipt of their replies a Committee of the Economic Advisory Council was appointed to sift the evidence, make recommendations, and remain in being in an advisory capacity. The report of this committee has just been issued in two parts, part I consisting of general information about colonial dietaries, a statement of the principles of nutrition and practical suggestions for improvement, and part II being a summary of information regarding each territorial unit of the Colonial Empire.

From this report it appears that colonial dietaries are predominantly vegetarian, only very small quantities of animal products, especially milk, being consumed; and many of the peoples depend on a single crop There is consequently a deficiency of first-class proteins, calcium, and phosphorus The dietary is also usually low in fats, fruits, and green leafy vegetables Deficiencies of all vitamins except D are widely reported The difficulty of distinguishing between the effects of a deficient dietary and those of an infection is emphasised The committee consider that the two main causes of malnutrition in the Colonies are (apart from diseases) the low standard of living and ignorance, often combined with prejudice. The problem is one of improvements in agricultural production, on which the colonial population principally depends A "balanced agriculture" is the answer *to an unbalanced dietary.*

The low consumption of milk and its products is striking in colonial dietaries. Little or no milk is consumed after weaning There are, it is true, dangers associated with the use of fresh milk in tropical climes and in sometimes primitive conditions Dried skimmed milk can be imported and is said to give better value for money than any other form of manufactured milk. Suggestions are also made for the further development of fisheries and for

the introduction of other crops, especially soya beans and ground nuts, and a valuable appendix, written by Dr B S Platt, shows how it is possible to live on well milled rice as the sole staple food without developing beriberi, if the following conditions are adhered to (1) the rice must be stored in such a way that it does not lose its vitamin B_1, (2) the rice must not be washed before being cooked, (3) there must be no superfluous water at the end of cooking, and (4) not less than 150 international units of vitamin B_1 must be supplied daily in the rest of the diet—e g, 6 oz of dried beans or 3 oz of ground nuts

DR WILLIAM BEAUMONT

THE main outlines of the extraordinary story of Alexis St Martin and of the energy and skill of William Beaumont in seizing on a unique opportunity are well known to every student of physiology, but probably very few appreciate the magnitude and importance of Beaumont's contribution to knowledge In fact there was but little detail of Beaumont's life or work available until the publication in 1912 of Dr Jesse Myer's "Life and Letters of Dr William Beaumont" The story is familiar An accidental gunshot wound received at close quarters left Alexis with a permanent gastric fistula beneath the remains of his rib So far was this injury from interfering with his general health or his digestive capacity that he lived to eighty three and was probably capable of much harder work than he was ever minded to undertake, for from many points of view Alexis was not an estimable character Beaumont had been called to the patient at the time of the injury and had confidently predicted a rapid death Contrary to his expectation Alexis survived, and Beaumont gave him the most devoted attention When the charity of the township was exhausted, he took him into his own household and continued his treatment for nearly two years after the accident By this time Alexis had regained his health and strength

Though Beaumont had been interested by the nature of the injury and by the opportunity which it had afforded him of seeing the actual processes of digestion, it was many months before he realised the unique chance for scientific experiment It is probable that at first he had carried out some investigations on the rate of digestion of various substances, but in a somewhat desultory fashion At all events, about two years after the accident Beaumont had begun a planned series of experiments, and he continued them for more than a year, when they were abruptly terminated by the disappearance of Alexis In spite of his best endeavours Beaumont failed to find any trace of Alexis for upwards of two years, and it was two more years before he was in a position to carry out further experiments, having taken Alexis into his household as a paid servant By this time Beaumont and Alexis had become famous, at any rate within a comparatively narrow circle, for it was not till the publication of Beaumont's book in 1833 that his researches became widely known Long before this, however, Surgeon General Lovell had realised Beaumont's value and, by generous furloughs and by making Alexis a sergeant in a detachment of orderlies, had rendered him most valuable assistance Indeed it is possible that without Lovell's aid Beaumont might have faltered in his purpose—but it is not probable, for the true scientific ardour which is obvious in all his work would not have recognised any barrier to be insurmountable Lovell's successor as Surgeon General was not equally in sympathy with Beaumont, and the clash between them ended in Beaumont's resignation of his commission From this time onwards till his death in 1853, twenty years after the publication of his book, he led the life of a busy and prosperous medical man in St Louis Throughout this period he made repeated attempts to get Alexis to return to him but without success

The work on which his fame rests was accomplished in the ten years between 1823 and 1833 What that work signified for the progress of the science of physiology is summed up in an appreciation by Professor Ivy, of Chicago, which is prefixed to a reprint of Myer's biography published this year[1] In spite of certain erroneous inferences, Beaumont's record of fact is so incontrovertible and stated in so scientific a method that Professor Ivy ranks him high in the field of original research and regards him not only as the first of American physiologists but also as the first American exponent of the true scientific method

EUTELEGENESIS

OUR U S A correspondent has already noted[2] the remarkable experiment in artificial insemination made by Dr Frances Seymour Mr and Mrs K had been married for eleven years and had been involuntarily childless The husband's semen contained 94 million highly motile spermatozoa per c cm and the motility index was within normal limits There were no discoverable defects in the wife's reproductive system and various therapeutic measures designed to promote fertility had proved ineffective Dr Seymour inseminated sixteen women, whose husbands were sterile, with Mr K's semen This step was taken with the consent and knowledge of the women concerned, though in several instances Mr K's religion and nationality differed from those of the sterile husbands It is further noteworthy that Mr K had the high intelligence quotient of 140 which, in Dr Seymour's words, "throws him in the genius group" No pregnancies ensued from these sixteen inseminations With the consent of the participants in the experiment, the same sixteen women were then inseminated with the semen of a man whose fertility had been proved by the fact that he was the father of two children This man's intelligence quotient of 120 again placed him above the average He was, moreover, an eminent figure in his profession and his wife, described as a highly intelligent college graduate gave full consent The sixteen volunteers and the wife of Mr K, who was also inseminated, all became pregnant

This novel experiment has several implications It proves, in the first place, that the presence of adequate numbers of motile and vital spermatozoa is not a necessary index of fertility, and it raises important legal questions which are the subject of a leading article in the issue[3] of the journal of the A M A which contained Dr Seymour's report The conclusion is reached that, in American law, children born of an artificial insemination by semen other than that of the woman's husband would be regarded as illegitimate The question of adoption proceedings therefore arises —

"The presumption of law that a child born during wedlock is legitimate is not absolute and conclusive under all circumstances Even at early common law the presumption was overcome by proof of the husband's sterility Today the presumption as to legitimacy is more easily controverted than it was in

1 London: Henry Kimpton 21s
2 *Lancet* 1939 1 1285
3 *J Amer med Ass* 1939, 112 183

earlier times. Now it is generally recognised by the courts that a child is illegitimate, though born or begotten during marriage, when it is impossible that its mother's husband could have been its father. Every species of legal evidence tending to this conclusion is admissible on the trial of the issue as to its legitimacy.

"In many instances of artificial insemination, perhaps in a great majority, the facts may never be known to any one other than husband and wife, and the physician involved. There is the possibility, however, that interested relatives may learn of the circumstances and may procure the evidence necessary to overcome the presumption of legitimacy and may thus deprive the child of a share of intestate property. It is the just due of the child that false pride or considerations of delicacy be put aside and that it be given, through adoption proceedings, the protection intended by the husband of the mother when he consents to the artificial insemination of his wife."

Dr. Seymour's experiment shows that artificial insemination can be used with a eugenic purpose and the word "eutelegenesis" has been suggested by Mr Herbert Brewer [4] to designate such an application of this measure. Its eugenic possibilities have further been discussed by Mr. H. J. Muller,[5] a pioneer in the field of experimental genetics. The possibilities of eutelegenesis are manifold and Dr. Seymour's experiment describes one of the simplest. It would clearly have been possible for Mrs K., and for the sixteen women collaborators in Dr Seymour's experiment, to have adopted children. But rather than adopt a child of alien and perhaps unknown parentage, they preferred to have a child of their own by a father of proved merit There are clearly grounds for regarding such a course as, in some respects at least, emotionally preferable to adoption. The mother has the experience of maternity and the father's attitude to the child might be regarded as comparable to that of a stepfather towards the children of his wife by a previous marriage. It would be interesting to know how far Dr Seymour's experiment would commend itself to couples in whom an undesired sterility is traceable to the husband.

DIPHTHERIA IMMUNISATION IN POLAND

In 1936 compulsory immunisation against diphtheria was adopted by Poland for children between the ages of one and ten years, an urgent incentive for this measure being the growing incidence of diphtheria in the country, for there were more than three times as many cases in 1937 as in 1926. In a communication to the French Academy of Medicine Hirszfeld,[6] of Warsaw, has traced the progress of this measure in terms of vital statistics It was necessary to pick out certain communities for his survey, because it has proved impracticable to apply the new law wholesale, without reference to social and geographical considerations The law seems to have been framed in an elastic spirit, for while allowing provisional exemptions under certain conditions it also permits of the extension of the age-limit above ten if necessary. In Lodz, where 80 per cent. of the child population has been immunised, the diphtheria morbidity was five times, and the diphtheria mortality fifteen times, greater among the non-immunised controls than among the immunised children of the same age in 1937. In Warsaw, on the other hand, only 60 per cent. of the child population has been artificially immunised, and here, to judge by the number of notifications, the diphtheria morbidity has apparently been uninfluenced by immunisation. Hirszfeld has alternative explanations for this fact The morbidity from diphtheria might have been even higher had immunisation not been partially effected, or immunisation may actually have enhanced the dangers for the non-immunised children by increasing the number of carriers of diphtheria—children who, had they not been immunised, would have contracted the disease and been isolated If his second suggestion is correct, half measures in diphtheria immunisation seem to be a doubtful blessing.

THE PERSONAL FACTOR

Scientists are human and being human tend to see their own work and that of others through the often distorting medium of their own personality, to be unfair to the unorthodox and original, and to put the claims of family or self-aggrandisement before the single-minded pursuit of truth The genius in consequence is often unrecognised or recognised too late In his "Scientists are Human" [1] Mr. D. L. Watson, Ph D, has assembled an impressive array of geniuses that never gained official or academic recognition, but being human himself he has rather over-weighted the instances in favour of his theory and under-weighted the others He allows that not every genius has died an embittered or thwarted man, but he does not seem to bring out that not all originality is genius, and that if the official scientist fails at times to appreciate the genius he also saves the world from much nonsense. Also, if the genius complains that one who came after him received the recognition denied to him, he must be sure that he gives due credit to those who preceded him. Dr. Watson has made some interesting contributions to a rather neglected aspect of scientific organisation. He finds a disproportionate emphasis placed on measurement, with a consequent neglect of the immeasurable Classification, abstraction and hypothesis are useful tools, but they must not be allowed to become ends in themselves The mental processes used in science have much in common with those used in the intuitive judgments of everyday life, and should be acknowledged as such. The student should be encouraged to respect his elasticity of mind rather than his infallibility, and for this purpose formal courses may prove a hindrance; their best value is for the student who is sufficiently mature to demand them. Dr Watson's central theme is then that scientists should appreciate the inevitable consequences of their humanity.

EUGEN BLEULER

Through the death of Professor Bleuler on July 15 Switzerland loses one of her most distinguished medical teachers and a psychiatrist whose name was familiar throughout the world Born in 1857 of yeoman stock at a village near Zürich, Bleuler found his natural affinity in mental medicine and after qualifying became psychiatric assistant in Zürich, Berne, Paris, London and Munich before his appointment, at the age of 29, to the headship of the Rheinau asylum near Schaffhausen. He brought new life into that ancient institution by introducing occupational therapy and putting the slighter cases under care at home He was one of the first asylum managers to recognise the value of Freud's teaching and he followed the developments of psycho analysis

so far as his realistic view and his acute judgment permitted After the retirement of his teacher and friend, Auguste Forel, Bleuler succeeded him in the chair of psychiatry at Zurich and became director of the Burghölzli where he came in contact with C G Jung and published in 1911 "Dementia præcox or the group of schizophrenia" This book, based as it was on personal observation and on the Freudian conception of the unconscious, made him famous at once in the psychiatric world. He took the view that the schizophrenic psychoses present organic symptoms amenable only to somatic treatment and others which can be psychologically understood and dealt with by psychotherapy He thus became the chief exponent of the psychological school in psychiatry and an originator of psychotherapy Bleuler was an outstanding teacher and his pupils now occupy the chairs of psychiatry at Zürich, Basle and Berne His teaching was not confined to his staff, he followed Forel in his crusade against alcoholism and an attempt to educate a wider public Bleuler's own textbook of psychiatry, first published in 1916, went through several editions and was translated into many languages, but his scientific achievement did not prevent him giving personal care to every administrative detail in his institution Modest in his own life, and a democrat at heart, his patients will remember him for his fatherly advice, during visiting hours at Burgholzli he was often to be found at the gate ready to give a friendly word to the relatives of patients It was the combination of intelligence, character, self discipline, industry and unfailing search after truth that enabled Eugen Bleuler to achieve what he did even within the span of 82 years

PROPRIETARY MEDICINE LEGISLATION

WHEN the Chancellor of the Exchequer intimated his decision to maintain the medicine stamp duties for another year he gave a plain hint that the Government was prepared to examine proposals for controlling the sale of proprietary medicines by a method which would have regard to some other form of tax and, at the same time, to what he called "the aspect of public health" In more than one quarter this has been taken as an invitation for suggestions which might be examined with a view to embodying them in a measure of legislation, and in the circumstances it would not be surprising if the various interests vested in the proprietary medicine trade as well as those who regard the question from the public-health aspect were giving the matter careful consideration Professional and trading interests are in opposition and the interests of the several trade categories are also divergent On the other hand the public interest is closely bound up with "the aspect of public health" and that should be the line of approach to the goal which the Government would naturally desire to reach Thus the ideal method of solving the problem would be one prompted by public opinion which has no axe to grind, and it would seem that a possible measure of legislation has already been devised by parties who have no interest to serve other than the well being of the community It is understood that a bill has been drafted by a group of members of both houses of Parliament which seeks to control the traffic in proprietary medicines by requiring (1) the registration both of proprietors and the articles which they manufacture, and (2) the confidential disclosure of formulæ to the Ministry of Health This draft bill also provides for the refusal to register proprietary articles whose composition is such that the articles cannot possibly produce the results claimed for them on the labels The aim of the bill is not to interfere with legitimate trade but to put a check on heartless chicanery

LOCAL AUTHORITIES AND VOLUNTARY HOSPITALS

THE Ministry of Health's last annual report (for the year 1937–38) expressed the opinion that local authorities might make still fuller use of their statutory powers to give financial help to voluntary hospitals The report summarised those powers and the relevant passage is conveniently reprinted in Memorandum No 132 issued by the Central Bureau of Hospital Information The memorandum tabulates information, supplied in response to inquiry from the bureau, of 25 instances of financial arrangements of a capital nature between voluntary hospitals and local authorities The statutory powers are to be found in the Public Health Act of 1936 First in order of importance to the hospital, perhaps, though not in the order devised by the draftsmen, is the power under section 181 (3) for a local authority to give reasonable subscriptions or donations to voluntary hospitals without entering into any agreement for the reception of patients The only limitation here is the stipulation that the expense so incurred in any year is not to exceed the product of a 1½d rate or such higher sum as the minister may specially approve. The memorandum seems to give no typical instance of a contribution of this kind, because usually the local authority puts up its money for specific facilities for patients Secondly, there is section 271, which on the face of it is a mere supplementary clause for interpreting the meaning of the word "provide" in the act This section enacts that any power of a council to provide buildings or other premises includes a power to equip them with necessary apparatus and instruments, and any power of a council to provide buildings, premises, accommodation, equipment or vehicles includes a power to make agreements for the use of any suitable buildings, premises accommodation, equipment or vehicles The result is that a local authority can agree with a voluntary hospital for the use of a complete block or wing in the hospital or for the use of X ray apparatus or ambulances Moreover, for such a purpose, the local authority can make a capital contribution to provide the buildings, apparatus or ambulances and can, with the minister's consent, raise a loan in order to do so It is presumably under this section that the West Sussex county council has provided the Royal West Sussex Hospital at Chichester with £4000 and obtained in return the joint use of the deep X ray therapy department So also at Scarborough the borough council has provided £12,500 (secured on a mortgage of the whole of the hospital building) and obtains a maternity ward of 12 beds Thirdly there are subsections (1) and (2) of section 181 which give local authorities as part of their general power to provide hospital accommodation for the sick the right to make arrangements with voluntary hospitals for the reception of patients As the Ministry of Health report points out the hospital can build accommodation with the help of a capital contribution in respect of which the local authority can borrow money, the local authority can also pay for the maintenance of patients treated in accommodation provided by the voluntary hospitals The Ministry observes that local authorities have made most use of this third statutory power The Hertford

shire county council, for instance, pays £2600 a year for thirty years for the use of 50 beds in the Hertford County Hospital, maintenance being at the rate of £1 per patient per week with a minimum of £21 per week (subject to periodical review) The Kesteven county council pays the Grantham Hospital £4368 a year for twenty years for the use of 24 beds for medical, surgical and maternity cases; this sum is intended to represent the cost of maintenance, remuneration of the medical staff and repayment of the capital cost, and the scale can be adjusted every three years according to any rise or fall in the average cost of maintenance Naturally there is great diversity in this type of arrangement. This does not entirely exhaust the statutory powers. There is also section 67 of the Poor Law Act of 1930, enabling the councils of counties and county boroughs, subject to different limitations, to make annual contributions to the support and maintenance of a hospital. Finally the local authorities can arrange for accommodation in a voluntary hospital for the specialised health services, such as maternity and child welfare and the *treatment of tuberculosis, venereal disease, and now* perhaps cancer. There is evidence also of helpful local cooperation in such instances as the Bath Corporation Act of 1937, where the city makes a not ungenerous exchange of land and provides the Royal Mineral Water Hospital (now the Royal Hospital for Rheumatic Diseases) with foundations on a new site raised and levelled at the expense of the corporation.

TAVISTOCK CLINIC

PLANS are now ready for carrying on the Tavistock Clinic in war-time Should an emergency arise the clinic will move immediately from Malet Place to the Orchard Wing of Westfield College, Hampstead, and all patients will be notified of the change Private practice by members of the staff will also be carried on at Westfield Those who are called up for service will be able to have their private work referred to their colleagues, and can arrange for all professional messages to be put through to Westfield College The finance of the private side of the clinic will be centralised and all work done will be on a cash basis After paying administrative and other expenses the first claim on the pool of private fees will be to make up the weekly salaries of all the medical staff who are doing whole-time work to the level of pay of a captain R A M C—namely, 11 guineas a week. The remaining members of the staff will declare their weekly earnings at the clinic office so that they can be taken into account in levelling up incomes Any surplus in the pool will be held in the bank for distribution later.

CONFERENCE ON CRIPPLES

NEARLY 500 delegates attended the fourth world conference of workers for cripples held in London last week under the presidency of Lord Nuffield. This conference, the fourth of its kind in ten years, had as its object the interchange of views between all those concerned in the re-equipment of cripples for the work of life. Mr. Elliot, who was present as Minister of Health and reviewed the recent astonishing development of orthopædics, asked the conference to substitute the word "handicapped" for "crippled" to convey the hopefulness of the present outlook. Some well-known surgeons were present at the conference, but not so much as surgeons as in virtue of their interest in problems of organisation, educational training and rehabilitation.

A NATIONAL EMERGENCY MEDICAL SERVICE

A SCHEME has now been agreed between the Minister of Health, the Secretary of State for Scotland and the Central Emergency Committee of the British Medical Association providing for a national hospital medical service for the treatment of casualties in war-time Doctors joining the service will assume for a period of three years a definite liability to serve in an emergency. The service will be recruited from medical practitioners other than those holding whole-time posts under the Government or local authorities. Those wishing to join should apply to the B M A, either directly or through their local branch, and not to the Ministry or Department of Health. There will be two classes of service, A and B.

WHOLE-TIME SERVICE

Class A.—Practitioners in this class will be called up for whole-time hospital service in war-time and will be liable to be transferred temporarily to any part of the country. Those needed at the outset will be called up immediately; others will be called up as required and in the meantime may be employed as if they were in class B. They will be paid on the following scale:—

(*a*) Consultant adviser	£1400
(*b*) Group officer	1300
(*c*) Medical superintendent—	
Hospital of 1000 beds and over	1200
" 750 " "	1000
" 300 " " *	900
(*d*) Officer in charge of surgical or medical division (hospitals of 500 beds and over)	950
(*e*) Surgeon or physician specialists	800
Other specialists in charge of departments	800
(*f*) Medical officers	550
(*g*) House officers	350

These salaries are on a resident basis An allowance of £100 a year will be paid where board and lodging are not supplied

* Special consideration will be given in the case of hospitals with less than 300 beds

PART-TIME SERVICE

Class B—Practitioners in this class will be liable for hospital service on a sessional basis in their own hospital area according to the needs of the moment They will be paid on the following scale for work done in hospitals:—

(*a*) For consultant and specialist work	£2 12*s* 6*d* per session of two hours' duration up to 5 sessions in any week, with £2 2*s* for other sessions, subject to a maximum payment of 120 guineas a quarter
(*b*) For general-practitioner work	£1 11*s* 6*d* per session of two hours' duration up to 5 sessions in any week, with £1 5*s* for other sessions, subject to a maximum payment of 75 guineas a quarter

There will be no uniform for those employed under the scheme, but whole-time members will have a distinguishing badge or other emblem

Doctors recruited for the service will be allocated to their war-time positions now. Thus there will be created in peace-time a complete system of casualty hospital staffs which will come into action automatically immediately war is declared. The maintenance in every area of an adequate number of private practitioners who will continue their ordinary work in war-time will be secured, and arrangements have been made by which the practices of those who take up full-time work will be temporarily carried on by other doctors Any doctor who is still uncertain as to the way in which he can best serve the nation in war-time should seek the advice of the local emergency committee of the B.M A. in his area

BRITISH MEDICAL ASSOCIATION

MEETING IN ABERDEEN

THE proceedings of the representative body, which opened on July 21 with Dr H G DAIN in the chair, were at first concerned with international tension and its consequences

Contact with Doctors Abroad

The debates began briskly with an attack on the council's majority decision to withdraw from the Association Professionelle Internationale des Médecins (A P I M) Defending this decision Sir KAYE LE FLEMING (chairman of council) said he had always been very keen on international medical coöperation, but was not convinced that the A.P I M has served any useful purpose or is likely to do so The attendance at its meetings was very small, they were too widely spaced for any considered policy to develop, and delegates must speak French As a means of enabling representatives of voluntary bodies to discuss medical problems the A P I M was a failure It had never discussed the disasters that have overcome sections of the profession abroad Lately the election of a Czech as president, and the choice of Prague as meeting place, had had to be quashed because a member from a totalitarian state said that otherwise his government would not let him attend Mr R SCOTT STEVENSON, leading the opposition for Marylebone asked whether this country is going to abandon all international conferences because they are conducted in French The A P I M was not the only body that is sparsely attended or has abandoned Czechoslovakia Other representatives said that the B M A must not withdraw from an organisation which it helped to bring to birth, that it must not foster the narrow nationalism now triumphing, and that it should lead rather than run away—improve the A P I M and not desert it Dr PETER MACDONALD (deputy chairman of the representative body) thought this the worst possible time at which to extinguish one of the last flickering flames of coöperation with other countries, and Mr MCADAM ECCLES believed withdrawal from the A.P I M would be a blow to the international medical societies of specialists Mr V ZACHARY COPE said that anything that enables people of different nations to compare notes is good, that the B M A, with its expanding influence, should be in contact with Europe as well as the Empire, and that it would be disastrous to dissociate British doctors from colleagues on the Continent at this particular juncture "If there is ever a time when professional people all over the world should keep together and give a lead this is it," said Dr C F T SCOTT The practical merits of the A P I M as a bond were seriously questioned by one or two speakers, but the meeting accepted the Marylebone view that the B M A should remain a constituent member of it

Refugee Doctors

Dr ERNEST WARD, for Torquay, criticised the council because, without consulting the representative body, it told the Home Secretary that the association had no objection to the admission of a further 50 refugee practitioners This led Sir KAYE LE FLEMING to explain the steps taken Before the B M A was consulted some 200 doctors came into this country to practise The council then protested and the Home Office agreed to consult it about the numbers henceforth permitted entry and the persons to be chosen When accepted the foreign doctor must study medicine here for two years before registration, and for seven years afterwards he would remain under supervision by the Home Office, which could decide where he is to work On these terms the B M A consented to the admission of 50 Austrians The further decision to take 50 Czechs had to be made at short notice, even before the council assembled, "and I would be ashamed," said Sir Kaye, "to meet this body and say we were not prepared to do for Czechoslovakian doctors what we have done for Austrian doctors" On hearing which, Torquay withdrew its objection

Dr J MELVIN, for Wandsworth, proposed a counterblast to the Trades Union Congress's light hearted demand for the admission of more foreign practitioners let the association agree to take one medical refugee for every thousand absorbed by other trades and callings But Dr A A LEWIS, speaking for Kensington, thought the protest undignified, and it went no further

Asked to disclose how many refugees have been admitted to the Medical Register during the past twelve months Sir KAYE LE FLEMING said that in 1938 the number was 103, of whom 35 have joined the association It was impossible to dissect the total so as to show the various grounds on which they secured registration

Preparations for Emergency

Sir KAYE LE FLEMING recalled that by last autumn the emergency register of practitioners contained the names of 96 per cent of the profession, with their qualifications and offers of service "we knew all about them" But it was then realised that the information cannot be used effectively unless all applications for doctors come through a single channel The present arrangement was that the Ministry of Health shall coördinate all requests from the services for medical personnel, and that military needs shall be met through the central medical emergency committee, which has been made fully representative of the profession Demands for doctors to care for the civil population must all go to the local emergency committee of the area, and allocations would be made locally subject to the consent of the central committee It had long been impossible to get an answer from the authorities about the status of doctors allocated to civilian hospitals, but the Government had now agreed to a scale of remuneration for the national hospital service, comparable to remuneration in the army Those provisionally appointed to it must say they will serve for three years

Brighton proposed that the cost of all this work by the central and local committees should be borne by the Government, and Prof R M F PICKEN also thought this fair, except in so far as the work is concerned with the protection of practices Sir KAYE LE FLEMING said that in the early stages the association asked for no money, but the maintenance of the register had been very expensive and the six clerks now employed were paid by the Government On the other hand he was strongly against asking the Exchequer to find all the necessary funds The work represented a contribution to the public welfare by the B M A, which had gained a priceless privilege in ensuring that the profession will manage its own

shire county council, for instance, pays £2600 a year for thirty years for the use of 50 beds in the Hertford County Hospital, maintenance being at the rate of £1 per patient per week with a minimum of £21 per week (subject to periodical review). The Kesteven county council pays the Grantham Hospital £4368 a year for twenty years for the use of 24 beds for medical, surgical and maternity cases; this sum is intended to represent the cost of maintenance, remuneration of the medical staff and repayment of the capital cost, and the scale can be adjusted every three years according to any rise or fall in the average cost of maintenance. Naturally there is great diversity in this type of arrangement This does not entirely exhaust the statutory powers. There is also section 67 of the Poor Law Act of 1930, enabling the councils of counties and county boroughs, subject to different limitations, to make annual contributions to the support and maintenance of a hospital. Finally the local authorities can arrange for accommodation in a voluntary hospital for the specialised health services, such as maternity and child welfare and the treatment of tuberculosis, venereal disease, and now perhaps cancer There is evidence also of helpful local cooperation in such instances as the Bath Corporation Act of 1937, where the city makes a not ungenerous exchange of land and provides the Royal Mineral Water Hospital (now the Royal Hospital for Rheumatic Diseases) with foundations on a new site raised and levelled at the expense of the corporation.

TAVISTOCK CLINIC

PLANS are now ready for carrying on the Tavistock Clinic in war-time Should an emergency arise the clinic will move immediately from Malet Place to the Orchard Wing of Westfield College, Hampstead, and all patients will be notified of the change Private practice by members of the staff will also be carried on at Westfield. Those who are called up for service will be able to have their private work referred to their colleagues, and can arrange for all professional messages to be put through to Westfield College. The finance of the private side of the clinic will be centralised and all work done will be on a cash basis After paying administrative and other expenses the first claim on the pool of private fees will be to make up the weekly salaries of all the medical staff who are doing whole-time work to the level of pay of a captain R A M.C —namely, 11 guineas a week The remaining members of the staff will declare their weekly earnings at the clinic office so that they can be taken into account in levelling up incomes Any surplus in the pool will be held in the bank for distribution later.

CONFERENCE ON CRIPPLES

NEARLY 500 delegates attended the fourth world conference of workers for cripples held in London last week under the presidency of Lord Nuffield. This conference, the fourth of its kind in ten years, had as its object the interchange of views between all those concerned in the re-equipment of cripples for the work of life. Mr. Elliot, who was present as Minister of Health and reviewed the recent astonishing development of orthopædics, asked the conference to substitute the word "handicapped" for "crippled" to convey the hopefulness of the present outlook. Some well-known surgeons were present at the conference, but not so much as surgeons as in virtue of their interest in problems of organisation, educational training and rehabilitation.

A NATIONAL EMERGENCY MEDICAL SERVICE

A SCHEME has now been agreed between the Minister of Health, the Secretary of State for Scotland and the Central Emergency Committee of the British Medical Association providing for a national hospital medical service for the treatment of casualties in war-time. Doctors joining the service will assume for a period of three years a definite liability to serve in an emergency. The service will be recruited from medical practitioners other than those holding whole-time posts under the Government or local authorities. Those wishing to join should apply to the B M A, either directly or through their local branch, and not to the Ministry or Department of Health. There will be two classes of service, A and B.

WHOLE-TIME SERVICE

Class A.—Practitioners in this class will be called up for whole-time hospital service in war-time and will be liable to be transferred temporarily to any part of the country. Those needed at the outset will be called up immediately; others will be called up as required and in the meantime may be employed as if they were in class B They will be paid on the following scale —

(*a*) Consultant adviser	£1400
(*b*) Group officer	1300
(*c*) Medical superintendent—	
Hospital of 1000 beds and over	1200
" 750 " "	1000
" 300 " " *	900
(*d*) Officer in charge of surgical or medical division (hospitals of 500 beds and over)	950
(*e*) Surgeon or physician specialists	800
Other specialists in charge of departments	800
(*f*) Medical officers	550
(*g*) House officers	350

These salaries are on a resident basis An allowance of £100 a year will be paid where board and lodging are not supplied

* Special consideration will be given in the case of hospitals with less than 300 beds

PART-TIME SERVICE

Class B—Practitioners in this class will be liable for hospital service on a sessional basis in their own hospital area according to the needs of the moment They will be paid on the following scale for work done in hospitals —

(*a*) For consultant and specialist work	£2 12*s* 6*d* per session of two hours' duration up to 5 sessions in any week, with £2 2*s* for other sessions, subject to a maximum payment of 120 guineas a quarter
(*b*) For general-practitioner work	£1 11*s* 6*d* per session of two hours' duration up to 5 sessions in any week, with £1 5*s* for other sessions, subject to a maximum payment of 75 guineas a quarter

There will be no uniform for those employed under the scheme, but whole-time members will have a distinguishing badge or other emblem

Doctors recruited for the service will be allocated to their war-time positions now. Thus there will be created in peace-time a complete system of casualty-hospital staffs which will come into action automatically immediately war is declared. The maintenance in every area of an adequate number of private practitioners who will continue their ordinary work in war-time will be secured, and arrangements have been made by which the practices of those who take up full-time work will be temporarily carried on by other doctors. Any doctor who is still uncertain as to the way in which he can best serve the nation in war-time should seek the advice of the local emergency committee of the B M A. in his area.
